Some leftist theorists note that the postmodern turn arose at the very moment that conservative political dominance decreased the prestige of leftist theory and practice. A crude “sociology of knowledge” of the postmodern turn might contend that, absent mass social movements contending for state power, left-wing academics retreat into the realm of pure theory. The rejoinder to this might be that postmodernism’s insistence on the relevance of the particular, local, and hybrid has had a salutary effect on limiting the imperial claims of “grand narratives.” Either way, analytic attempts of macrostructural and historically oriented social theorists to discern the interaction between social agency and social structure are likely to remain a major theme within social science. And the postmodern concern with the fate of marginalized groups would seem to push the discussion ethically beyond postmodernism’s emphasis on the local and particular. The quasi-universal concepts of citizenship and global human rights may not have an irrefutable, a priori basis in a fixed human nature, but if human beings cannot develop shared understandings and values that bridge their differences, it is unlikely that the emancipatory, democratic project embraced by many postmodern theorists will ever be realized.

**POSTNATIONALISM**

The term *postnationalism* refers to the critique of the concept of the nation as the central organizing principle of modern political identity and government. According to postnationalism, the category of the nation is no longer sufficient to describe the fundamentals of political identity or state government. In a postnational context it becomes necessary to move beyond the idea that a homogeneous national identity is the natural integrating factor of modern political community. Further, postnationalism questions the idea that the sovereign nation-state is indispensable to the order of international affairs and the functioning of the domestic rule of law.

**THE CRITIQUE OF NATIONALISM**

Postnationalism arose out of the critique of nationalism. It was only at the end of the eighteenth century that citizenship and national identity came together, in the figure of nationalism, for the functional purpose of providing a principle of integration that could serve to mobilize the transition from royal sovereignty to popular sovereignty. Nationalism provided the solution to the twin problems of secular legitimation and complex integration in the wake of religious schism and republican revolution. While citizenship describes a purely legal relation within a political community, in modern times the tendency has been to tie it to an identity that points beyond
the political sphere. Political membership based upon the principle of a unique national culture presupposes an existential difference between peoples. According to this logic, in order for a nation to be free it must remain homogeneous and independent from alien influence, necessitating not only separation but also suspicion of others as corrupting forces. According to this logic, diversity becomes a threat. The concept of postnationalism seeks to break this tie between citizenship and ethnic identity or existential difference. The use of postnationalism, in this sense, is most common in debates about the future of Europe and the European Union.

THE DEMISE OF THE NATION-STATE
Postnationalism also arose from the critique of the nation-state. A large literature surrounding the topic of “globalization” has called into question the institutional capacity of the nation-state to fulfill its role as an all-encompassing form of political organization. As a result of globalization, the world’s political, economic, cultural, technological, and military forces have established connections across national borders with increasing facility. Beyond the borders of the nation-state, transnational institutional authorities have emerged and become increasingly powerful. External authorities have a growing influence over the internal affairs of states, and traditional understandings of state sovereignty have been called into question by the growth of international systems of decision making, law, and security. Thus the proliferation of international decision-making bodies has tended to extend the sphere of authority beyond the nation-state. The consolidation of the World Trade Organization, for example, signifies the appearance of an international institution that claims the authority to overrule national governments. As a result, some have argued that the twenty-first century will be an era of postnationalism, in which regional organizations, such as the European Union, or international organizations, such as the United Nations, will be the principal organs of political authority, rather than the nation-state.

POSTSTRUCTURALISM
Though often equated, poststructuralism and postmodernism are distinct intellectual phenomena. Most well-known poststructuralists, especially the French philosophers Michel Foucault (1926–1984) and Jacques Derrida (1930–2004), eschewed any association with postmodernism. Only Jean-François Lyotard (1924–1998) can be said to straddle both of these movements.

Postmodernism is as much a sensibility or cultural mood as a specific doctrine. It implies a break with modern modes of experiencing time and space, the dissolution of coherent meanings and narratives, and changes in media of communication. Politically, postmodernism is often seen as reflecting new forms of political organization such as global capitalism or new social movements that reflect cultural difference rather than unity. While aesthetic modernists often waved the fragmentary nature of modern experience into a unity, postmodernists reject the assumptions of unity as metaphysical residues of modern reason. Poststructuralism shares the postmodernist unease with totality, but it refuses to herald new forms of experience of culture, politics, or thought that would replace the modern. Rather, poststructuralism is a form (one of several) of modernity’s self-criticism. Poststructuralists do not entirely reject important concepts of modernity, such as knowledge, rights, or subjectivity, but they subject these concepts to a critique that dethrones them from an imperial or originary position. They seek to avoid the totalitarian and utopian pretensions of reason and subject them to a permanent critique.

Along with Derrida, Foucault, and Lyotard, prominent poststructuralists include Gilles Deleuze (1925–1995), Roland Barthes (1915–1980), Julia Kristeva, and Jean-Luc Nancy. As the name suggests, poststructuralism arose as an intellectual movement in reaction to the shortcomings of structuralist approaches in linguistics and the social sciences. Ferdinand de Saussure (1857–1913) in linguistics and Claude Lévi-Strauss in anthropology developed theories that explained language and social action, respectively, as the product of objective structures alone. While structuralists recognized that systems of meaning were essentially arbitrary systems of linguistic difference, and not reflections of transtemporal or ultimate meaning, they were still guilty, according to critics, of a form of rationalism, in which a fixed object of meaning could be studied by objectifying procedures of social science. This explanatory strategy leads to difficulties explaining the nature of involvements of participants who had to take up and employ meanings. It cannot tell us, to use a well-known example, how a gift is given or whether it is given properly.

Poststructuralists such as Derrida argued that meaning has a performative, practical dimension not associated
with an originating subjectivity. Meaning is renewed or transformed through such performances. Poststructuralists employed this practical dimension, however, to show the limits of the projects of theory not only in structuralism but in modern subjective reason as well. This critique took many forms, from Barthes’ criticism of the unified literary text, to Kristeva’s notion that meaning is intertextual without reference to any fixed outside order, to Deleuze’s nomad thought, and to Derrida’s criticism of the logocentrism of Western thought and its desire for plenitude and fullness.

Poststructuralists, hermeneutic, phenomenological, and critical approaches rely implicitly on totality and thus do not fully escape the grip of Western rationalism. The nature of the practical or performative dimension always provides resistance to fullness or totality. Derrida, for example, argued that meaning was indeterminate, that it was not fixed through any objective or theoretical process. Meaning is not a representation of an objective world but the disclosure of a world of meaning within which we make sense of things. However, linguistic meanings are never complete or univocal, but always fissured through ambiguity and contradiction. From another angle, Foucault argued that systems of knowledge are always formed by power interpretations, and hence are never pure or interest-free as the traditional metaphysical notion of objectivity would hold. Poststructuralism is a form of negative critique. It stresses the nonidentity between enacted performances that may always create a novel meaning and a fixed ideal sense. The indeterminacy of linguistic performance undermines the possibility of ideal meaning found in a transcendental subjectivity. In the tradition of negative critique, poststructuralists stress the nonidentity between enacting a performance and the ideal concepts of totality and practical understanding. The aim of this critique is to undermine the latent (and sometimes explicit) totalitarian assumptions of an overextended notion of reason, and thus its political thrust as well. There is no single political movement or ideology that captures all of reality, nor any utopian goal in human actions. The political is always in the particular.

Critics have equated poststructuralism with anarchic or amoral strains of postmodernism. The poststructuralist stress on the indeterminacy and internal inconsistency of thought is linked to a free-floating conceptual apparatus driven by desire and power. Poststructuralism rejects the primacy of subjectivity altogether and in contrast employs a view of social reality as fictional, without references to an outside reality. Other critics have pointed to the possible political quietism of a view that denies the viability of general or universal values. These judgments have proven to be incorrect. Poststructuralists have displaced subjectivity from its imperial role as an origin, recognizing its produced character, but they have not rejected the subject, knowledge, or even a constructive politics. After an initial phase that placed questions of language and power at the center, poststructuralism has taken an ethical turn. Many of the major figures of poststructuralism, including Foucault, Derrida, Nancy, and Lyotard, have devoted considerable work to ethics.

There are two major strains of poststructuralist ethics. The first approach, the power-interpretive view, is associated with Foucault and Deleuze. It holds with Friedrich Nietzsche (1844–1900) that dominance is the establishment of new interpretations. The second, which is associated with Derrida, Nancy, and Lyotard, is an ethics of otherness. The ethical is equated with a nondoninating otherness that is beyond being and ontology. This interpretation is heavily influenced by the work of the Lithuanian-born philosopher Emmanuel Lévinas (1906–1995).

Foucault, and for the most part Deleuze, follow Nietzsche in seeing interpretation as a form of power. In Nietzsche’s view, the creation of new interpretations established what is true or false and moral or immoral. Power discloses a world of meaning. Foucault takes this formative power in an Aristotelian direction in order to view the ethical as a form of work on the self, an interpolation of self and other. Interpretive thought is not pure strategy because it draws on an expressive world-forming capacity.

The ethics of otherness draws on the poststructuralist idea of the resistance of performance to full interpretation. Against what he saw as a Hegelian notion of totality, as well as Martin Heidegger’s (1889–1976) notion of homeland, Lévinas rejected the view of mutual recognition as metaphysical residue. Mutual recognition extends only to the familiar, the similar, or the identical. Such an ethics could not account for the outsider or the stranger—they can never be assimilated. Recalling another radical critic of G. W. F. Hegel (1770–1831), the outsider is a nonperson who belongs to no corporate entity. An ethics of otherness is beyond the realm of being or ontology. It can never be made explicit, but requires an attitude of openness or welcoming toward the excluded other.

Derrida, Nancy, and Lyotard all begin from Lévinas’s ethics of otherness. Derrida employs what might be called a linguistic-critical approach to otherness. The limits of deconstruction are found in the notion of justice. Respect for the other is the one premise that can never be deconstructed. Derrida gives a non-Kantian account of universal justice as a reception of the other that is the precondition of any language. This leads not only to an ethics of otherness, but to a conception of democracy that is linked to the ethical demands of the other. Democracy is never fulfilled, never entirely specified, but it is always yet to be. Still, Derrida’s use of otherness as a critique of ethics, politics, and philosophy denied any specific poli-
tics or doctrine. No explicit account of democracy or an ethos of otherness is possible.

In contrast, Nancy’s ethical and political reflections draw on phenomenology and on Heidegger’s notion of Mitsein (being with others) in order to develop a notion of community as incorporating otherness. Identity and difference constitute each other.

Lyotard’s position is an important variation of the ethics of otherness. He begins with a notion of speech acts that gives more credence to everyday understanding than does Derrida or Nancy. Like neo-Aristotelians, Lyotard puts the faculty of judgment at the center of political reflections. Despite this similarity with interpretive approaches, Lyotard relies on Lévinas’s notion of the ethical as beyond the dialogical nature of ordinary speech and action. Justice is not an ineliminable basis of his theory. Instead, justice is a political capacity that steers between the realms of action. Lyotard’s conception of justice, like Hannah Arendt’s (1906–1975), is drawn from Immanuel Kant’s (1724–1804) critique of judgment.

Critics of poststructuralism, such as Todd May, argue that an ethics of otherness must fail. While poststructuralists correctly identify the limits of foundationalism, they often err in equating all theoretical accounts with foundationalism. Domains of inquiry that are constituted through difference or otherness are difficult to define or delimit and are inherently contradictory. Even sympathetic critics, such as Simon Critchley, find the excessive emphasis on otherness to be problematic. Critical theories that grow out of Jürgen Habermas’s work have held that accountability is not just theoretical but a feature of practical activity. This postmetaphysical version of mutual recognition and mutual understanding does not, in their view, require the identity of subjects, but fosters the inclusion of the other into ethics without the need for totality.

Poststructuralism has had a significant impact on the social sciences, especially in regard to the social construction of knowledge, communication, and methodologies. Poststructuralists challenge the traditional model of objectivity, which claims to be able to represent or describe social reality. They dissent from interpretive approaches in holding that the social construction of knowledge raises an irresolvable dilemma on the nature of truth. Anthropologists, for example, have had to address questions about the adequacy of their descriptions of other cultures. They doubt whether one can represent social reality in any way. Poststructuralist anthropology often contends that anthropologists create the very phenomenon they seek to study. More recently, many social scientists have linked poststructuralism to a postpositivist perspective that overcomes the division between natural science and social science. Here, all science is a kind of pragmatic production shaped by social motives of power and dominance.

Sociologists, while raising similar questions about the objectivity of knowledge, have employed poststructuralist perspectives to study the production of knowledge. In opposition to what they see as the interpretive theorists’ emphasis on the formative power of intentional action, poststructural sociologists want to emphasize the way subjects themselves are formed by regimes of knowledge. Foucault’s *The Order of Things* (1970) is an example of this type of approach, as is Bruno Latour’s study of scientific practices. Latour sees science as constructed by the laboratory and its instruments, not independent of them.

In communications theory, Jean Baudrillard’s influential work analyzes the way in which subjectivity is constructed as a consumer of material good and products. Charles Lemert developed a general sociological approach based on poststructuralism. Though not strictly in the camp of poststructuralism, Bent Flyvbjerg’s attempt to formulate a practically oriented phronetic social science draws heavily on Foucault’s linkage of power and knowledge. In addition, much of Pierre Bourdieu’s (1930–2002) writing on symbolic power and the construction of social hierarchies of knowledge in universities and in “culture” was influenced by Heidegger and poststructuralism.

Post-Traumatic Stress

The term post-traumatic stress is used to describe an individual’s reaction to an experience of serious, life-threatening trauma. The trauma can come from a single event—such as a physical assault, a car accident, a natural disaster, or witnessing the death of another—or it can come through a series of events, such as chronic abuse or combat experiences. Symptoms include flashbacks, nightmares, intrusive thoughts about the event, decreased ability to concentrate, panic, memory loss, and mood changes (e.g., depression, irritability). Individuals may experience these symptoms immediately following the event, or it may be months to years before symptoms first appear. Symptoms occur in a range of intensity and longevity; for some the symptoms become debilitating.

For many individuals, post-traumatic symptoms diminish over time or with appropriate mental health services, support from friends and family, and other therapeutic or supportive interventions. Although individuals continue to feel the effects of the trauma in some form, most report that the symptoms subside or are minimal, and the effects can be managed so that the individual does not feel burdened. However, as reported by the National Center for Post-Traumatic Stress Disorder (NCPTSD), for 8 percent of men and 20 percent of women, the symptoms do not diminish and develop into post-traumatic stress disorder (PTSD). Furthermore for 30 percent of these individuals, PTSD becomes a chronic condition that persists throughout their lifetimes. PTSD is distinguished from post-traumatic stress by the intensity and duration of the symptoms and by three characteristics of symptoms: they are reexperienced, there is hyperarousal or sensitivity to stimuli, and there is avoidance of triggering stimuli.

Brian J. Caterino
The American Psychiatric Association (APA) outlines the PTSD diagnostic criteria in the *Diagnostic and Statistical Manual-IV-TR (DSM)*:

A. The person has been exposed to a traumatic event in which both of the following were present:
   (1) The person experienced, witnessed, or was confronted with an event or events that involved actual or threatened death or serious injury, or a threat to the physical integrity of self or others; (2) The person’s response involved intense fear, helplessness, or horror. Note: In children, this may be expressed instead by disorganizing or agitated behavior.

B. The traumatic event is persistently re-experienced in one (or more) of the following ways:
   (1) Recurrent and intrusive distressing recollections of the event, including images, thoughts, or perceptions. Note: In young children, repetitive play may occur in which themes or aspects of the trauma are expressed; (2) Recurrent distressing dreams of the event. Note: In children, there may be frightening dreams without recognizable content; (3) Acting or feeling as if the traumatic event were recurring (including a sense of reliving the experience, illusions, hallucinations, and dissociative flashback episodes, including those that occur on awakening or when intoxicated). Note: In young children, trauma-specific reenactment may occur; (4) Intense psychological distress at exposure to internal or external cues that symbolize or resemble an aspect of the traumatic event.

C. Persistent avoidance of stimuli associated with the trauma and numbing of general responsiveness (not present before the trauma), as indicated by three (or more) of the following:
   (1) Efforts to avoid thoughts, feelings, or conversation associated with the trauma; (2) Efforts to avoid activities, places, or people that arouse recollections of the trauma; (3) Inability to recall an important aspect of the trauma; (4) Markedly diminished interest or participation in significant activities; (5) Feeling of detachment or estrangement from others; (6) Restricted range of affect (e.g., unable to have loving feelings); (7) Sense of a foreshortened future (e.g., does not expect to have a career, marriage, children, or a normal life span).

D. Persistent symptoms of increased arousal (not present before the trauma), as indicated by two (or more) of the following:
   (1) Difficulty falling asleep or staying asleep; (2) Irritability or outbursts of anger; (3) Difficulty concentrating; (4) Hypervigilance; (5) Exaggerated startle response; (6) Duration of the disturbance (symptoms in Criteria B, C, and D) is more than 1 month; (7) The disturbance causes clinically significant dis-

Although these criteria are well-defined, diagnosis of PTSD is a complicated process in part because PTSD symptoms are similar to those of many other psychiatric disorders (e.g., depression), anxiety disorders, and psychotic disorders. In addition many individuals feel shamed or embarrassed by the event or their reactions and may not report the full extent of their symptoms. A multimodal approach is considered to be the most effective for accurately diagnosing PTSD. The NCPTSD suggests an approach including a clinical interview, completion of standardized assessment tools, and a physical assessment.

Statistics from the National Mental Health Association indicate that at least 5.2 million Americans (3.6 percent of U.S. adults) experience PTSD during the course of a year, and nearly 8 percent of Americans will experience PTSD at some point in their lifetimes. Researchers have shown that although PTSD can occur at any age, females develop PTSD at twice the rate of males regardless of their age.

PTSD is a relatively new term within the mental health field, having first appeared in the *DSM* in 1980. However, the concept appeared in the historical medical literature as early as during the Civil War as the term Da Costa’s Syndrome. In World War I, World War II, and the Korean War shell shock, battle fatigue, and war neurosis were used to describe the troubling symptoms experienced by combat soldiers. The U.S. government did not begin systematically to focus on the origins, symptoms, and treatment of PTSD until the era following the Vietnam War. The military research on PTSD was drawn on by those working in noncombat trauma areas to better understand the impact of various forms of trauma on individuals.

If left untreated, PTSD symptoms can have an impact on all areas of a person’s life and can cause both psychological and physical illnesses. Physical effects include chronic pain conditions, immune system disorders, and neurological system symptoms (i.e., memory loss, coordination of the fear response). Cognitive symptoms include distractedness and an inability to analyze events because of physical changes in the hippocampus (the brain region responsible for such processes). Emotional effects include grief, rage, sorrow, numbness, despair, and guilt, among others, as manifested in behaviors such as difficulties with interpersonal relationships.
and maintaining employment, addiction, isolation, and self-mutilation or self-injury. According to the NCPTSD, a majority of those with PTSD (88 percent of men and 79 percent of women) also met the criteria for a secondary psychiatric diagnosis, meaning that PTSD puts individuals at risk of other mental health disorders.

The National Child Traumatic Stress Network reports that children and adolescents are especially vulnerable to developing PTSD after experiencing a traumatic event because of their limited ability to process information, their lack of cognitive sophistication, and general issues of maturity. Children may exhibit additional symptoms, such as toileting problems, development of a disturbed sense of self, low self-esteem, academic struggles, or symptoms that interfere with a normal developmental task.

Although much remains unknown about PTSD, there are promising treatments that have been successful in treating individuals with PTSD. Some of these include prolonged exposure therapy, cognitive-behavioral therapy, family therapy, group therapy, and some drug therapies.

POTRON, MAURICE

1872–1942

Father Maurice Potron, a French Jesuit and a graduate of France's prestigious Ecole Polytechnique with a Ph.D. in mathematics, published major, but surprisingly little known, mathematical-economic papers between 1911 and 1941. His writings include three major findings.

First, in mathematics, he published a demonstration about the existence of solutions of nonnegative matrices (or “linear substitutions” as he called them) as early as 1911, before Ferdinand Georg Frobenius (1849–1917) did so in 1912. In 1908 and 1909 Oskar Perron (1880–1975) and Frobenius had only demonstrated theorems related to strictly positive matrices.

Second, in the same paper, Potron, while trying to reconcile social justice (“fair” price, “fair” wage) and economic interdependencies, was the first to apply Perron-Frobenius's theorems on a Leontief-type model, in order to find the conditions for the existence of a fair economic equilibrium, a “satisfactory economic regime” in Potron's words, allowing simultaneous adequacy between the consumption structure and that of production and work capacities, and adequacy between price and wage levels. As far as we know, nobody had used Perron-Frobenius's theorem in economics before World War II (1939–1945).

Third, in 1912 Potron laid the foundations of future input-output analysis, offering a detailed study of the expenses supported by his baker to produce a two-kilogram loaf of bread. The extension of such a study to other industries would allow precise calculation of the “effective satisfactory regime of production-consumption and prices-wages” (Potron 1912, p. 19). Indeed, he used matrices to describe the economic interdependency between products and branches. The concept of a “technical coefficient” was used in 1912 to promote a central planning office whose mission would be to organize the economy according to social Catholic doctrine. Thus, the invention of input-output matrices is undoubtedly due not to Wassily Leontief (1906–1999) but to Potron (1912), since Leontief’s “The Balance of the Economy of the USSR” was published in 1925 and The Structure of the American Economy, his greatest book, in 1941. The existence of a “calculations bureau” (bureau des calculs) would constitute the only way to achieve a “satisfactory regime.” This concern led Potron to put forward, in 1936, the use of Gauss-Lanczos’s iterative method in order to help the planning office deal with the huge dimensions of the matrix, a method widely used in algorithms today.

As early as 1912, Potron introduced the number of working days per year as a relevant parameter of the viability of an economic system. He was also concerned with the possibility of demand inadequacy: in what has been called Potron's law, he shows how an increase in demand will raise general activity and revenue. Since he lacked academic training in economics, Potron's economic approach is mainly explained by his intellectual and social environment (Abraham-Frois and Lendjel 2004). Catholic doctrine (as expressed in 1891 in Pope Leo XIII’s encyclical
**POULTANTZAS, NICOS**

**1936–1979**

Famous for his concept of the “relative-autonomy of the state” as well as for his debate with Ralph Miliband (1924–1994), Nicos Poulantzas was a formative neo-Marxist theorist of politics. Born into a prominent family in Greece, Poulantzas studied law at the University of Athens before moving to France, where he completed his doctoral studies in the philosophy of law. During this time, he was closely aligned with the existential Marxism of Jean-Paul Sartre (1905–1980) and Simone de Beauvoir (1908–1986), and he was a contributor to their journal *Les Temps modernes* (Modern Times). Poulantzas, however, began moving away from existentialism in 1966 and increasingly came to be influenced by the “structuralist” Marxism of Louis Althusser (1918–1990); it is largely in this context, as an Althusserian or structuralist, that Poulantzas has come to be known.

In 1969 the *New Left Review* published Poulantzas’s critical review of Miliband’s book *The State in Capitalist Society* (1969). This review was the first volley in what came to be known as the Miliband-Poulantzas debate. The debate largely hinged on whether the class bias of the state was a product of the class origins and affiliations of those individuals who occupied the top positions within state institutions (Miliband) or whether the class bias of the state was more a product of its structures and functions (Poulantzas). Beyond separating Marxists into what may have been an overstated divide of “instrumentalist” and “structuralist” camps, the debate highlighted a renewed Marxist interest in the theory of politics, and it foreshadowed and provoked an intense growth of research on the state, a still ongoing body of inquiry often referred to as state theory.

Poulantzas’s most important work in this context was *Political Power and Social Classes* (1968). It is in this work that he first developed the idea of the relative autonomy of the state. According to Poulantzas, for the state to properly function as a capitalist state it must be able to go against the individual and particular interests of capitalists in order to act in their general/class interests; the state must be “relatively autonomous” from the interests and demands of capitalists. This also implied that the state could not be reduced to some reflection of economic relations or interests, as more orthodox Marxists had often done. Poulantzas argued that, as economic agents, capitalists tend to be divided and competitive. The state provides the institutional space for various factions of the capitalist class, as well as other powerful classes, to come together and form long-term strategies and alliances; this is what Poulantzas termed the *power-bloc*. At the same time, the state disorganizes the working class by dividing them into individuals/citizens, what he termed the *isolation effect*.

---

*Gilbert Abraham-Frois*

*Emeric Lendjel*
Poulantzas's *Fascism and Dictatorship* (1970) was an empirical case study based on his theoretical work. He examined the class foundations of fascism and understood the fascist state as an exceptional form of the capitalist state. He argued that fascism was not inevitable or some natural stage in the development of capitalism and thus that it, as a type of response to a crisis of politics, could be repeated in the future. Poulantzas applied similar ideas in one of the first Marxist studies of democratization, *The Crisis of the Dictatorships: Spain, Portugal, Greece* (1975). There he argued that the rise of democracy in each country was the outcome of a political conflict between two key factions of the capitalist class, the domestic and comprador bourgeoisie.

In Poulantzas's subsequent theoretical work, he made a key contribution to class theory when he argued against traditional “in itself” and “for itself” definitions and contended that classes do not exist outside of conflict and struggle, that classes only exist as an ensemble of practices. In *Classes in Contemporary Capitalism* (1974), he also examined the political implications of the growing transnationalization of capital (one of the first Marxist examinations of globalization), and he examined the growth of the “new” petite bourgeoisie.

In his last book, *State, Power, Socialism* (1978), he critiqued the theories of Michel Foucault (1926–1984) and Giles Deleuze (1925–1995), among many others, and refined his previous theories. Poulantzas now defined the state as a social relationship and argued that the question of its relative autonomy was a function of class struggle. Since the state was a condensation of the class struggle it was always in flux and contested; no one class had complete control, and the state always had to take the interests of the dominated classes into consideration. The degree of this relative autonomy would thus be a historical variable and would change in accordance with the content and intensity of the political struggles of the day.

Poulantzas’s theoretical positions were also reflected in his political affinities and activities. His emphasis against economic determinism was an anti-Stalinist stance and reflected Poulantzas’s support of democratic socialism and the radical democratic positions of Rosa Luxemburg (1870–1919), Antonio Gramsci (1891–1937), and the Eurocommunist movements of the time. Poulantzas was an active member of many leftist organizations, such as the Communist Party of the Interior in Greece and of the CFDT (Confédération française démocratique du travail; French Democratic Confederation of Labor) in France, and he often contributed to the newspapers and journals of these organizations as well as to the popular press. Given his emphasis on questions of political strategy and his support of a democratic transition to socialism (as well as the appropriation of his ideas by radical democratic currents in France, Italy, and especially Portugal, Spain, and Greece), Poulantzas is often considered to be a key theorist of Eurocommunism. Despite his untimely death at the age of forty-three, Poulantzas’s conceptual contributions and political sensibilities continue to be relevant to a wide range of concerns within contemporary social science.

**POVERTY**

Poverty is among the most central problems of economics, and its alleviation is a long-standing challenge for economists and policy makers alike. The Millennium Development Goals (MDG) adopted by the United Nations in 2000 aim to lower the fraction of the world’s poor by the year 2015 to half its 1990 level, where “poor” includes those subsisting on less than $1 a day. This description of poverty is close to the $1.08-per-day poverty line (in 1993 dollars) adopted by the World Bank. Defined by the $1 cut-off, in 1998 one in five people in the world (1.2 billion) were poor, and they were concentrated in South Asia (522 million), sub-Saharan Africa (291 million), and East Asia (278 million).

**WORLDWIDE DISTRIBUTION OF POVERTY**

Measured in terms of certain basic capabilities—health, education, political voice, credit—these regional poverty patterns persist. The 2004 Human Development Report states that sub-Saharan Africa accounts for 22 percent of the world’s malnourished population and 42 percent of primary school-age children not in school. For East Asia the corresponding figures are 25 percent and 13 percent, and for South Asia, they are 37 percent and 31 percent, respectively. Thus, the $1-a-day measure seems to do a reasonable job of capturing other relevant dimensions of poverty.

How do those with less than $1 a day really live? Based on household level surveys across thirteen countries, Abhijit Banerjee and Esther Duflo (2007) give us a vivid picture: They often work multiple odd jobs (and not only in agriculture); frequently migrate temporarily for...
work; own few assets other than land; lack access to credit and insurance; get poor-quality health care and education (if at all); are frequently malnourished; spend much (but not all) of their income on food (50–75%), alcohol and tobacco (resisting temptations to spend more), and festivals (but few other forms of entertainment); and importantly, although they do feel the pinch of poverty, their self-reported levels of happiness and health are not particularly low. If this poverty cut-off were doubled to just $2 a day, nearly half the world’s people would be deemed poor (2.8 billion)—and shockingly, they consume less in a month than what the nonpoor consume in a single day.

These figures are grim, but to gain some perspective on them and assess how realistic the MDG are, we need to measure the progress the world has made in alleviating poverty. Taking the long view, the drop in the poverty rate—from 84 percent in 1980 to 50 percent in 1950, to 24 percent in 1992—and the rise in life expectancy—from twenty-seven years to sixty-one years over the same period (Bourguignon and Morrison 2002)—is dramatic. Over a shorter period it is less so. According to the World Bank, the poverty rate worldwide has fallen from 28.7 percent in 1987 to 24.3 percent in 1998 (World Bank 2007). (These numbers are somewhat sensitive to the time period and data sources used; Angus Deaton [2002] points out that this can be explained by the use of different underlying data sources, but there is less disagreement of the pattern of changes than in levels.) Once again, there is sharp regional variation—from 26.6 percent to 15.3 percent in East Asia (mostly China) and 44 percent to 40 percent in South Asia, but stagnant around 46 percent in Africa, with an increase of 50 million in the region’s poor. These sharp regional variations in poverty reduction emphasize the question of what the underlying causes of poverty are. Not surprisingly, there are multiple views on what is the “right” answer.

ALleviating POVERTY: Is MARKET-DRIVEN GROWTH ENOUGH?

The dominant view of the 1980s, the “Washington Consensus,” still prevalent in some influential quarters (such as the International Monetary Fund), is that growth is the best answer to the poverty problem and that market-friendly policies are best suited to achieving growth. Does the data support this view? There is strong evidence of positive correlation between growth and poverty reduction—which, of course, is not the same as causation. Based on numbers from sixty countries with data for more than one year, Timothy Besley and Robin Burgess (2003) find that poverty rates are very responsive to changes in income per capita (elasticity = - 0.73 worldwide), but yet again, with large regional differences (-1.0 in East Asia versus - 0.49 in sub-Saharan Africa). They conclude that, given historical growth rates of per capita income, growth alone is unlikely to help achieve the poverty reduction targets set in the MDG in most regions (Besley and Burgess 2003). As for evidence of market-driven growth, it is now widely agreed that the most prominent growth story of the past three decades, the “East Asian miracle,” involved active government intervention in markets (Amsden 2001). Overall, support for the Washington Consensus view does exist, but it is not overwhelming. As a practical matter, many countries have had a less than favorable experience with certain aspects of “stabilization plans” based on this view—a policy package typically involving openness to trade and foreign capital markets, restrictive monetary and fiscal policies, privatization of state-owned enterprises, and deregulation of important markets. Concerted international action to tackle poverty, in the form of foreign aid, has been well below the United Nations’s aid target of 0.7 percent of gross domestic product of the G7 countries (the United States, France, Germany, Italy, Japan, the United Kingdom, and Canada). But even if that aid were available, it would be only one-third of what is needed to achieve the MDG. Collectively, these realities have forced a search for alternative explanations for and solutions to the poverty problem.

THE INSTITUTIONAL APPROACH TO POVERTY REDUCTION

A shift in the thinking on poverty is also being driven by a deeper theoretical understanding of both market failure and government failure—that is, how market imperfections deny the poor a chance to make the investments needed to rise out of poverty, and why governments are not always effective in making up for this lapse. One important conclusion emerging from research in this area is the need for sound domestic institutions to promote growth and poverty reduction—more so than a country’s geographical or “cultural” legacies. A natural consequence of this finding is a call—by the World Bank (World Bank 2003) and by academic economists—for a wider set of institutional reforms, including promoting democracy and other forms of political voice for the poor, the rule of law, property rights for the poor, increasing government accountability, and reducing corruption. There has been a steady trickle of evidence supporting the favorable impact of sound institutions on outcomes for the poor: for example, how property rights over land in urban areas in Peru help the poor gain access to credit, increase labor supply, and be more productive (De Soto 2000; Field 2002); how political representation for women in India results in more funds for public goods they care about (Chattopadhyay and Duflo 2004); and how a newspaper campaign concerning government accountability in-
creased the resources reaching public schools in Uganda (Reinikka and Svensson 2001).

**SERVICE DELIVERY: GETTING “TRICKLE DOWN” RIGHT**

Although progress on institutional reform is crucial, it can be slow. A parallel approach is a package of policy measures that target poverty and redistribute resources to the poor through schools and health clinics, promoting small businesses, access to credit, better social safety nets, and so on. Here, theoretical research has helped to explain why certain redistribution mechanisms—for instance, in-kind rather than cash transfers—can deliver greater equity and growth when there are market imperfections. This research has shed light on the political economy of public good provision, with insights into suitable incentives for policy makers, providers, and program recipients. On the ground, the better programs have worked through effective design and implementation. For instance, Mexico’s Progresa program involves cash benefits for women and their families that are conditional upon the child(ren) being sent to school and being taken for health check-ups. Microfinance—pioneered by Mohammad Yunus of the Grameen Bank—uses a combination of “peer monitoring” and group liability for borrowers, which makes possible “micro” loans to those too poor to offer collateral. One common feature of both these programs is that they channel resources to poor households through women. Such a gender-based strategy of redistribution is gaining support, given widespread evidence of women’s tendency to spend more resources on children’s welfare and human capital, relative to men (Haddad, Hoddinott, and Alderman 1987). It has also been recognized as a viable solution to the problem of child labor and low schooling, breaking the vicious link from current to future poverty. While there is strong evidence for the positive impact of Progresa (Schultz 2004), ongoing work is evaluating and refining the design of microfinance initiatives.

More broadly, a combination of empirical and, more recently, experimental work is helping design and systematically evaluate a host of service-delivery mechanisms, including the effect of improved child health on school attendance (Kremer-Miguel 2004); the impact of more rural bank branches on poverty (Burgess and Pande 2002); and the impact of corruption in the issuance of drivers’ licenses by the government (Bertrand, Djankov, Hanna, and Mullainathan 2007).

**NEW PERSPECTIVES ON POVERTY**

As part of these experiments with program design and implementation, economists have sometimes found it hard to rationally explain certain choices that the poor make, be it with regard to savings, or technology adoption (Ashraf et al. 2006; Duflo et al. 2006). This gives rise to an exciting new behavioral economics approach to poverty that seeks to understand decisions of the poor from not just an economic perspective, but also a psychological one. Insight into the strengths and weaknesses of governments and markets also blurs the line between private- and public-service delivery (Besley and Ghatak 2004), giving rise to innovative approaches such as the Advanced Commitment for Vaccines initiative. Some even argue that the world’s poor constitute not just an obligation for the rich, but also a vital, untapped market (Prahalad 2004).

At the international level, however, some important issues that affect poverty remain difficult to resolve. Globalization and trade have been a boon to some countries (or some areas within countries), but a bane to others, creating greater income insecurity for the poor in some developing and developed economies. International agreements on trade and immigration, intellectual property issues, and environmental pollution have not always been favorable to poor economies. These remain areas where large strides can be made toward reduction of global poverty.

POVERTY, INDICES OF

A poverty index measures the level of poverty in a society. In measuring the level of poverty, a poverty line or poverty threshold, usually stated in terms of income, is defined to divide the society into two separate groups. An individual is poor if that individual lives below the poverty line.

THE HEADCOUNT RATIO AND THE INCOME-GAP RATIO

The traditional poverty index is the headcount ratio, which is the proportion of the average income shortfall of the poor to the poverty line. If \( \mu_p \) is the average income of the poor and \( z \) is the poverty line, the income-gap ratio is

\[
\frac{1 - \left( \frac{\mu_p}{z} \right)}{1} \times 100\%
\]

Another poverty index that sometimes is used is the income-gap ratio, which is the percentage of the average income shortfall of the poor to the poverty line. If \( z \) is the average income of the poor, then

\[
H = \frac{m}{n} \text{ or } \frac{m}{n} \times 100\%
\]

Both poverty indices, however, have serious problems in measuring the poverty level of a society adequately. For example, the headcount ratio does not consider how far a poor individual is below the poverty line; an individual just below the line and an individual far below it are treated the same in the calculation. Although the income-gap ratio does not have this problem, it does not reflect how incomes are distributed among the poor. Whether they are equally poor or some of them are desperately poor, the same level of poverty is determined. Additionally, the income-gap ratio does not deal with the number of the poor; it considers only the average income of the poor. Intuitively, for the same average income of the poor, the society should have more poverty if more people fall into poverty.

THE AXIOMATIC APPROACH

Since the publication of Amartya Sen’s 1976 work on poverty measurement, the construction and evaluation of poverty indices have followed an axiomatic approach. In this approach, ideal properties for poverty measurement are formulated as axioms and a poverty index is generated to satisfy those axioms. The following are the key axioms for poverty measurement: The focus axiom states that the poverty index is not affected by a change in a nonpoor individual’s income as long as that individual remains nonpoor. The restricted continuity axiom states that the poverty index is continuous in poor incomes in that a
small change in a poor individual’s income should not lead to a large change in the poverty level. The monotonicity axiom states that all else the same, a decrease in a poor individual’s income should increase the overall level of poverty in the society. The weak transfer axiom states that all else the same, a transfer of income from a poor individual to a poorer individual should decrease the overall level of poverty. The subgroup consistency axiom states that if the society is divided into different subsocieties (such as the different states in the United States), all else the same, an increase in the poverty level of a subsociety also should increase the overall level of poverty of the society. The increasing poverty line axiom states that the poverty index should increase as the poverty line increases. Additionally, a poverty index should satisfy the unit consistency axiom: If one society (say, the United States) has more poverty than another society (say, the United Kingdom) when all incomes and the poverty line are measured in one currency unit (e.g., U.S. dollars), the conclusion should hold when another currency (e.g., British pounds) is used.

The headcount ratio does not satisfy the monotonicity axiom, the weak transfer axiom, or the increasing poverty line axiom. The income-gap ratio violates the weak transfer axiom and the increasing poverty line axiom.

Sen (1976) proposed the first axiomatic-based poverty index. Suppose all individuals’ incomes are arranged in increasing order and \( x_i \) is the \( i \)th individual’s income, then \( x_1 \leq x_2 \leq \ldots \leq x_n \). The Sen poverty index is

\[
S = \frac{2}{(m+1)a} \sum_{i=1}^{m} (z-x_i)(m+1-i),
\]

which also can be written as

\[
S = \frac{2}{n} \sum_{i=1}^{m} \left(1 - \frac{x_i}{z}\right)\left(1 - \frac{i}{m+1}\right) - H[I + (1-I)G_z \frac{m}{m+1}],
\]

where \( H \) is the headcount ratio, \( I \) is the income-gap ratio, and \( G_z \) is the Gini coefficient of the poor incomes. The Gini coefficient is twice the area between the Lorenz curve of the poor incomes and the 45-degree diagonal line. A slightly modified version of the Sen index is the Thon poverty index:

\[
T = \frac{2}{(n+1)a} \sum_{i=1}^{m} (z-x_i)(n+1-i)
\]

Other poverty indices include the Chakravarty poverty index:

\[
C = \frac{1}{n} \sum_{i=1}^{m} \left[1 - \left(\frac{x_i}{z}\right)^\epsilon\right] \quad \text{with } 0 < \epsilon < 1
\]

the Foster-Greer-Thorbecke poverty index:

\[
FGT = \frac{1}{n} \sum_{i=1}^{m} \left(1 - \frac{x_i}{z}\right)^\alpha \quad \text{with } \alpha \geq 0
\]

the Watts poverty index:

\[
W = \frac{1}{n} \sum_{i=1}^{m} (\ln z - \ln x_i)
\]

and the Kolm poverty index:

\[
K = \frac{1}{n} \sum_{i=1}^{m} (\rho^{a-1} - 1) \quad \text{with } \sigma > 0
\]

Both the Sen and Thon indices satisfy all the axioms listed above except the subgroup consistency axiom; the Chakravarty index, the Foster-Greer-Thorbecke index, and the Watts index satisfy all the axioms; and the Kolm index satisfies all the axioms except the unit consistency axiom. All these new poverty indices are referred to as distribution-sensitive indices because they satisfy the weak transfer axiom. The differences among these poverty indices lie in the ways in which the shortfall of each poor income to the poverty line is characterized and the ways in which those shortfalls across all individuals are aggregated into an overall index of poverty. For example, for the headcount ratio, each individual’s shortfall is assigned a value of one if the individual is poor and zero if the individual is nonpoor, and the overall poverty level is the simple average of those shortfalls (zeros and ones). For the Sen poverty index, each individual’s shortfall is recorded by \( 1 - \frac{x_i}{z} \) if the individual is poor and zero if the individual is nonpoor, and the overall poverty is the weighted average of those shortfalls, with the weight being \( 1 - \frac{i}{m+1} \), which is the relative rank of that individual among the poor. For the Watts poverty index, each individual’s shortfall is recorded by \( \ln z - \ln x_i \) if the individual is poor and zero if the individual is nonpoor, and the overall poverty is the simple average of those shortfalls.

**CALCULATING THE POVERTY LEVEL**

To calculate the poverty level of a society, one needs to define the poverty line and choose a poverty index. The definition of the poverty line varies from society to society. In the United States, the official poverty line initially was developed by Mollie Orshansky of the Social Security Administration in 1963–1964 and adjusted each year thereafter for inflation. The U.S. poverty line is regarded as an absolute poverty line because it was calculated as the minimum amount of resources needed for living at a point in time and is not affected by changes in the entire
income distribution. Because the minimum amount of resources needed for living depends on the specific society, the calculated absolute poverty line tends to vary from society to society. For example, an individual with an income at the U.S. poverty line would be regarded as rich in some developing countries. In poverty studies, especially in international comparisons of poverty, another type of poverty line—the relative poverty line—has been used. A relative poverty line is specified as a point in the distribution of income (e.g., one-half of the mean or median income), and the line is updated automatically over time for changes in the distribution.

Because the use of any specific poverty line, whether absolute or relative, is somewhat arbitrary, a range of poverty lines often are used to check the robustness of poverty comparisons. The resulting conditions for poverty comparisons are closely related to the conditions of stochastic dominance (Foster and Shorrocks 1988) and Lorenz dominance, which is based on comparisons of Lorenz curves. Similarly, the choice of a specific poverty index in poverty comparisons is somewhat arbitrary in light of the fact that there are multiple poverty indices that satisfy the same set of poverty axioms. If, for a specific poverty line, all poverty indices that satisfy certain axioms are used in poverty comparisons, the resulting conditions are also related to the conditions of stochastic dominance (Atkinson 1987) and Lorenz dominance.

**POVERTY, URBAN**

For well over a century and a half, the urban poor have been an object of intense contemplation among scholars, politicians, philanthropists, activists, and policy makers, and the topic of urban poverty has been one of the most controversial in the field of urban studies. Alternatively reviled or pitied, the urban poor tend to be characterized in academic and popular discourse as either undeserving, irrational, passive, pathological, apathetic, and in need of charity and moral reform or as deserving, resilient, exploited, and oppressed. Accordingly, explanations for the causes of urban poverty have, for the most part, vacillated between blaming the poor for their own impoverishment and explaining impoverishment in terms of urban political economy.

Research on urban poverty first gained prominence in nineteenth-century Europe and the United States as industrialization transformed the urban landscape. Its roots were primarily in early social reformism, which built on investigative journalism with survey research to make poverty visible so that it could be reckoned with by the burgeoning middle classes. In England, social reformer Charles Booth, for example, followed the earlier work of journalists Henry Mayhew and Andrew Mearns to gain widespread attention for his classificatory survey of the laboring classes, *Life and Labour of the People of London* (1902). In the United States, journalist Jacob Riis published the still famous *How the Other Half Lives* (1890). Soon thereafter, Hull House settlement founder Jane Addams spearheaded the publication of *Hull House Maps and Papers* (1895), revealing the distinctive pattern of immigration, wage inequality, and residential segregation that characterized American cities at the time.

As the first empirical studies of poverty in European and American cities, the work published by these social reformers is widely considered to be the precursor to modern social scientific poverty studies. Importantly, these studies were largely descriptive and were designed to be systematic in their classifications of the poor and in their depictions of the illicit commerce, violence, deprivation, and sloth that was sometimes present in urban neighborhoods. They were also focused squarely on the question of urban political economy, with class, wages, and employment as central categories of analysis. As the first study to establish a direct link between industrialization, the labor process, and the depreciation of living conditions in overcrowded slums, Friedrich Engels's *The Condition of the Working Class in England in 1844* became an early classic of this approach.

The rise of Chicago School sociology in the early twentieth century reoriented poverty studies away from urban political economy toward “social ecology.” Less interested in class than in assimilation and social disorganization among immigrants, the Chicago approach sought to explain industrialization, commerce, and residential distribution as natural occurrences in the urban environment (Park et al. 1925). In this formulation, poverty and segregation were understood as part of a nat-
ural process of ecological succession, in which poor and segregated neighborhoods were seen as “natural areas” where new immigrants were oriented to the city, giving them a foothold before their eventual accommodation with and assimilation into the more affluent mainstream. In a series of important and highly influential field and ethnographic studies on such topics as juvenile delinquency, gangs, hobos, and slums, the Chicago School provided the social scientific basis for the understanding of urban poverty, which its protagonists tended to view as a consequence of social deviance and neighborhood disorganization. E. Franklin Frazier’s The Negro Family in Chicago (1932) and The Negro Family in the United States (1939) gained wide influence in poverty studies by downplaying the importance of racial inequality, establishing a powerful connection between poverty and family structure, and arguing in particular that the matriarchal black family was “pathologically” disorganized and that it therefore perpetuated poverty. (It should be noted, however, that Frazier ultimately viewed family disorganization as temporary and that he was a strong advocate for incorporation of black men into the industrial workforce [O’Conner 2001].) In contrast, St. Clair Drake and Horace Cayton, also trained at Chicago, published Black Metropolis (1945). Like Du Bois’s The Philadelphia Negro (1899) before it, they placed a stronger emphasis on the role of racial inequality in the production and reproduction of black inner-city poverty.

The influence of the Chicago School’s poverty-as-cultural-pathology argument grew in the poverty scholarship and public-policy work of the 1960s and 1970s. Notably, anthropologist Oscar Lewis, best known for his widely disseminated “culture of poverty” thesis, linked behavior with the persistence of poverty (Lewis 1966). He argued that a significant faction of the poor were caught in an intergenerational quagmire of dysfunctional values and behaviors. This argument resonated with and reinforced the dominant policy positions that emerged as poverty was “rediscovered” in America in the 1960s during the War on Poverty. Famously, Lewis’s influence can be seen in Daniel Patrick Moynihan’s 1965 report to President Johnson, The Negro Family: A Case for National Action, which relied heavily on the “culture of poverty” thesis to describe black “ghetto” poverty and familial “dysfunction.” Many social scientists rebutted Lewis’s culturalist explanations for social “disorganization” with work showing that the consumption, labor market participation, and kinship patterns among the poor were not “dysfunctional,” irrational, or self-destructive but rather survival strategies that made sense given economic constraints (see, for example, Stack 1974; Liebow 1967; Valentine 1978).

In the 1980s and 1990s, the controversy around the “culture of poverty” thesis replayed itself as the underclass debate, which focused on the poorest of the poor in cities struggling to remake themselves under postindustrial conditions. Also centered around the behaviors of black inner-city residents, the debate this time focused on their social “isolation” and “dislocation.” Pundits and policy makers on the right argued that poverty was caused by poor people’s “dependency” on welfare programs (Murray 1984; Mead 1992). In rebuttal, left-liberal scholars countered the moralist formulations of the right with demographic analyses demonstrating the “structural” roots of impoverishment. William Julius Wilson (1987, 1996), among others, showed that public policies such as affirmative action, which enabled residential mobility for middle-class blacks, combined with labor market restructuring in deindustrializing cities to create an isolated underclass of chronically jobless inner-city residents. Both sides of the underclass debate were critiqued by left-leaning scholars for downplaying the persistence of racial and gender discrimination in labor markets, housing policies, and tax policies, and for perpetuating the image of the pathological poor (Goode and Maskovsky 2001; O’Conner 2001). Recent research on urban poverty has redirected attention once again to urban political economy. In the aftermath of the 1996 welfare reform, the popularity of the poverty-as-cultural-pathology argument has abated significantly, and new policy-centered work has documented the plight of the U.S. working poor, who are not able to earn wages high enough to pull them out of poverty. More significantly, as global cities paradigms have become more influential in urban studies, the idea that urban poverty is a consequence of global shifts in economy, politics, and governance has once again taken center stage. Whereas some European Third Way scholars have shifted their focus away from poverty toward social exclusion (e.g., Giddens 1998), others have directed critical attention to the political economy of the new global inner city. In the global North, gentrification and other redevelopment strategies are displacing low-income residents from central cities (Hackworth 2007). In the global South, slums are proliferating in large measure because of new migration patterns that correspond with global shifts in industrial and agricultural production patterns (Davis 2006). Of particular interest in this work is attention to the polarizing effects of neoliberalism on cities across the world (Harvey 2005). This new work resonates with scholarship that understands poverty as fundamentally a political problem, one that is shaped dramatically by forms of activism, urban or otherwise, that either include or exclude the impoverished residents who live in cities across the globe (Maskovsky 2001; see also Piven and Cloward 1977).

POWER

Power is a central concept in the social and political sciences. It is also commonplace in everyday discussions: We often refer to a political party getting into power, or to the power of governments or individuals to perform a particular action or achieve a certain result, or to someone having power over another, or to a country being a superpower. Power would appear to be self-evident. However, power is an extremely elusive concept, and there are numerous disagreements over its definition, foundation, function, and operation. Power remains, as Steven Lukes says, an “essentially contested” concept (1974, p. 26).

Power is usually associated with the bringing about of consequences. However, what these consequences are, whether or not they are intended, how they are actually brought about, who brings them about and in whose interests—are all a matter of unresolved debate across a number of different disciplines. It is not possible here to give an exhaustive list of these controversies, or to touch on all the many questions regarding the nature and exercise of power. There are, however, several major areas of contention that should be mentioned:

1. Should power be seen in terms of the actions or capacities of individual agents, or should it be seen as deriving from broader social structures?
2. Is power a resource or capacity that can lie dormant, or does it only exist when it is exercised?
3. Does power refer to the ability to achieve certain desired outcomes, or is it a relationship between agents where one exercises power over another?

4. Does power necessarily involve domination, coercion, or constraint, or can it be based on consent?

5. Is power exercised only where the consequences of a certain action are intended, or do unintended or unforeseen consequences also count as evidence of the exercise of power?

The remainder of the entry will explore a number of key theories and debates about power, which refer to several of the questions outlined above. It will also trace a certain logical development in the theorization of power from pluralist-behavioralism to structuralism to poststructuralism.

**THE THREE DIMENSIONS OF POWER**

The idea that power has three dimensions or “faces” comes from Lukes, who argues that the formula for power—*A has power over B to the extent that he can get B to do something that he would not otherwise do*—can be seen as operating in three distinguishable, yet interrelated, ways. The first face of power is usually associated with Robert Dahl who, along with Polsby (1963) and Wolfinger (1971), tried to show that power in the U.S. political system was distributed pluralistically. In doing so, they were opposing the “ruling elite” theorists such as Mills (1956), who believed that power was concentrated in the hands of a dominant group in society. In his study of local politics in the New Haven area of Connecticut—which he took as a microcosm of the broader distribution of power in American society—Dahl argued that there was no empirical evidence to support the idea of a ruling elite, and that, in fact, different groups were influential over different areas of policymaking (1961). Dahl’s analysis contained the implicit idea that there are plural centers of power in a democratic society. More importantly, its central focus was on decision-making behavior in cases where there is an observable conflict of interests. For Dahl, power is the ability to affect another’s decision-making: A exercises power over B when he can get B to make a decision that he would not otherwise make.

However, this idea of power as decision-making was criticized for being too one-dimensional. Peter Bachrach and Morton Baratz argued that power also has a hidden or covert dimension—a “second face” (1962). Power involves not only decision-making, but also what they call nondecision-making. This refers to the ability of dominant elites to “set the political agenda” in such a way that certain issues are prevented from being aired, thus precluding the very possibility of a decision being made about them. In situations of conflict, there is often a “mobilization of bias” against certain interests. The mass media would be an example of this: Whether consciously or unconsciously, it reinforces dominant values and practices, thereby delegitimating or marginalizing opposing viewpoints and preventing potential issues from becoming actual issues. In this paradigm, power operates not necessarily by directly influencing B’s decision-making, but by preventing B from raising concerns that might be detrimental to A’s preferences.

Lukes, however, contends that even this understanding of power was limited, because, like the pluralist-behavioralist view, it assumed that power is only exercised in situations of observable conflict between different interests. But what if it were the case that power functioned in such a way as to prevent conflict from arising in the first place (1974)? Here Lukes points to an even more insidious dimension of power—its “third face”—where power operates not simply by A getting B to do what he does not want to do, but by shaping B’s thoughts and desires in such a way that B does what A wants him to do as if it were a free and autonomous act. In other words, power may operate as a form of subtle thought-control or manipulation, and may cause someone to act, not according to his own interests, but in the interests of those who are exercising this power. What is being suggested here is that what we think we want and is in our best interests may not actually be so—our preferences may be shaped by external influences. Here we might think of the advertising industry, which sells us products that we do not necessarily need or even want, by manipulating our desires. This distinction Lukes draws between subjective interests and real interests is problematic, as discussed below, but his analysis of power is nonetheless interesting for the way it moves away from the domain of individual decision-making behavior, toward some notion of an overall structuring of the ideas and values that shape individual behavior.

**STRUCTURALISM AND MARXISM**

The structuralist argument is that power derives not so much from individual or even collective agents, but from their place in a broader social structure. In other words, it is the structural position of agents that allows them to exercise power over others. Marxists like Nicos Poulantzas argue, for instance, that in a relationship of class conflict, the economic and political power of the bourgeoisie—and its capacity to realize its interests—derives from its structural location within the capitalist system. In his debate with Ralph Miliband—who suggested that the class bias of the state could be explained by the privileged background and class allegiances of those who manned
the state apparatus (1969)—Poulantzas argued that Miliband's view places too much emphasis on individual behavior, and neglects the effects of structural relations in the capitalist system (1973). In Poulantzas's view, power derives from the ensemble of structures that make up capitalist society, which shapes relations between classes and allows one class to dominate others.

FOUCAULT AND POSTSTRUCTURALISM
Michel Foucault further radicalizes the concept of power by taking it beyond questions of both individual behavior and structure. For Foucault, power is a non-derivative concept that cannot be reduced to the preferences of individual agents, economic classes, or even the structural requirements of the capitalist system. Rather, power must be studied in its own right. Here he introduces a number of important methodological innovations. Firstly, the focus must be on the “how” of power—because power only exists when it is being exercised. There is no mysterious substance called power that can lie dormant without being exercised: Indeed, Foucault goes so far as to suggest that power “as such” does not exist (1994, p. 336).

Secondly, power is relational, rather than an individual or structural capacity: That is to say, power is a mutual relation between agents—both individual and collective. Power is a way of acting on the actions of others. This implies, thirdly, a certain freedom of action on the part of both agents in a power relationship. The power relationship presupposes that agents are able to act differently, that they have a range of actions open to them, and that power involves constraining or influencing these actions. Foucault argues, for instance, that slavery is not a power relationship because there is no possibility of the slave acting differently. In this sense, power is not a zero-sum game as many suggest: Rather, it involves a dynamic interplay between agents. Fourthly, then, while power is not the same as coercion, neither is it a matter of consent, as Arendt (1969) or Parsons (1969) would claim. While power constrains, there is always the possibility of there being resistance to it, even in situations of domination, where the normally free and reciprocal flow of power becomes congealed.

However, the question of resistance in Foucault’s theory of power is also ambiguous and problematic (see Newman 2001; 2004). This is because Foucault sees power as being not only repressive and prohibitive, but also productive: Power produces and incites (1978). Unlike Lukes, who sees power as distorting the subject’s “real interests,” Foucault believes that this notion of “real interests” is an essentialist illusion manufactured by power itself. Power intersects with discourses and “regimes of truth” to construct the very identity of the subject. While this avoids the dubious notion of “real interests,” it would seem, at the same time, to undermine the idea of a firm ontological and normative foundation for resistance to power: The subject who resists power is at the same time constructed by it. Foucault’s theory of power raises as many questions as it answers, and it should not be thought that he has revealed some elusive “fourth dimension” of power beyond which we cannot proceed any further. However, by focusing on the “how” of power, and by seeing power in terms of relationships rather than as a substance or capacity, Foucault has considerably advanced our understanding of the concept.

POWER, POLITICAL
Political power is commonly defined as the ability or potential to influence outcomes. Yet, there are several interpretations of this definition. To some scholars, it is the ability to control outcomes or shape the behavior of others. For instance, if A has power over B, A can coerce B to do things that B would not otherwise do. Thus, political power is conceived of as a coercive or control mechanism. To others, political power is simply a relative and self-oriented term: A's power is equal to B's or A has more or less power than B, but A and B do not necessarily have a coercive power over each other. Still others conceive political power as a public good that in a democratic society is shared by everyone. The foregoing three concepts seem to be unrelated but they, as will become clear later, actually describe different levels of power at different points in time.

HISTORICAL PERSPECTIVES
Understanding the concept of political power is enhanced if analyzed with respect to different political systems. Most societies have a history of autocratic systems. Modern democracies have been established only since the advent of the Industrial Revolution. During the long history of autocratic rule, societies were governed by monarchs, warlords, and their subordinates. Political power rested upon a single person or a handful of individuals. Going back to the beginning of political history, one finds that the first leaders were probably those who had above normal social skills, ambition, and motivation. Over time, however, political power often passed to the children or families of the rulers, regardless of merit. Power was used to amass wealth, and wealth, in turn, brought more power to the ruling elites, leading to a more skewed distribution of power. The masses had little or no political or civil rights. Accession to power became a function of being a member of the royal family or the ruling elite. The conceptualization of political power as a coercive or control mechanism, A having power over B, is grounded on the experiences of autocratic rule. The Industrial Revolution, beginning in countries like England and Sweden, changed that relationship by gradually diffusing power from the ruling elites to the masses.

The concept of political power as a public good seems to be based on the experiences of ancient and modern democracies. In the classical Greek democracy, the people were both the rulers and the ruled. Political power was equally or almost equally shared among citizens. In modern democracies, political leaders are elected by the people and are considered to be representatives of the people. Political leaders are expected to make decisions that, on average, benefit the interests of their respective societies. Leaders who are unaccountable or unresponsive to the interests of the people are unlikely to be reelected. The fear of loss of office, in part, motivates leaders to excel in their job performance. In modern democracies (unlike in classical ones) citizens, for the most part, possess power in different magnitudes. For instance, although all citizens have the right to vote and are treated equally before the law, individuals do not have an equal chance of influencing public policies or winning the highest elected offices. Thus, the idea that power is a public good or is shared evenly by all in modern democracies is empirically unsupported. The thesis describes what ought to happen, not what actually happens, in modern democracies. Nevertheless, power as a public good, or the perfect equality of power, may be considered a theoretical ideal, one end of the political power continuum, and democratic societies can be judged by how far removed they are from that ideal.

DIFFUSION OF POLITICAL POWER
From Greek philosopher Aristotle to seventeenth-century thinker James Harrington to socialist Karl Marx, many have argued that the distribution of power in a given society is influenced by the distribution of wealth and education or the level of socioeconomic development. The more wealthy and educated an individual is, the more power he or she will have. Informed and affluent citizens in modern democracies have acquired greater power and fundamental political and civil rights, including the right to vote, to assemble, to run for office, to due process, and to freedom of speech.

Citizens combine their individualized power to form interest groups and political parties to make sure that their interests are protected and fostered. Accession to a position of leadership also has, for the most part, become a function of an individual's wealth, education, and, to a certain extent, personal charisma. Leaders are elected to serve the people, not necessarily to earn more power. The authority and coercive rights of leaders in democracies, unlike in autocracies, is often institutionalized, power that is impersonal and resides in the state.
POLITICAL POWER: DYNAMIC OR STATIC?
The fact that political systems have evolved from autocracies to democracies, at least in most industrial societies, may indicate that the distribution of political power is a process or a dynamic, as opposed to a static, phenomenon. The three conceptualizations of political power—power as a coercive or control mechanism, power as a relative and self-oriented term, and power as a public good—may indeed be a continuum, different points in space and time. Thus, autocracies are political systems in which the distribution of power is concentrated in the hands of a few individuals. Democracies, in contrast, are political systems in which political power, in addition to basic procedural rights such as one-person-one-vote and equality before the law, is widely diffused among individuals. Older democracies, such as those in England, evolved from autocracies only after centuries of gradual and incremental political reforms. During this long period of political change, political power of the traditional elites and the masses have been minimized and maximized, respectively. Given the presence of some asymmetry in the distribution of power, even in modern industrial democracies, and assuming that economic development will continue to grow, there is no reason to assume that democracies will fail to evolve further. Indeed, the weaknesses of the concepts of power as a coercive or control mechanism and power as a public good are, respectively, that they fail to account for the changing nature of power and the fact that power parity among individuals has not in practice been achieved in modern democracies. It is not clear that such power parity will ever be achieved. But how do researchers measure the continuous nature of political power?

Political power may be redefined as the probability of attaining the most important office in a given state, the presidency or the prime ministry. The fact that not all individuals are interested in becoming president or prime minister or the fact that only one individual can attain the highest office is not important. Rather attaining such office is important as a yardstick for calculating the level of power an individual possesses. Thus, the probabilities of winning the highest office for each individual, and hence each person’s level of power, would lie between 0 and 1. The foregoing describes the concept of political power as a relative and self-oriented term: A’s power is equal to B’s or the former possesses more or less power than the latter. Given that political power is hard to quantify, however, income distribution can be a proxy for political power. Thus, the chances of each individual winning the highest office are estimated by using income levels; the higher the income of an individual, the higher the probability he or she will become a leader. The probability of winning the most important office for an individual in an ideal democracy, in which the number of adult citizens is equal to $N$ and in which power is perfectly equal among individuals, would be $1/N$. However, because of inherent differences in merit among individuals, ideal democracy or a perfect equality of power will not likely be achieved. Democracies embrace individual freedom and a market economic system, which result in some citizens having more power than others. What then is the most plausible distribution of power that in the future?

Gizachew Tiruneh posits that political power in democracies will, in the long run, likely be normally distributed or take the form of a bell-curve (2004). Early twenty-first century industrial democracies have an uneven distribution of power (and income) where the mean or average citizen is to right of center. That is, the distribution of power and income are skewed toward or in favor of the upper classes. As the level of democracy, propelled mainly by continuous socioeconomic development, increases or the level of power diffuses over time, the mean citizen will gravitate to the center of the normal curve (where the preponderant majority or the middle class is located), and, once settled at the center, will have the most decisive voice and power in democratic politics. Because those individuals to the right of the mean have, in theory, more power than those to the left of the mean and most leaders may come out of the former group, the political agendas and policies of leaders will likely be dictated by the preferences of the mean citizen. The normal distribution of power represents a democratic system whose quality or degree is likely to be optimal. In this stage of political development, the levels of democracy and power become nearly identical. Tiruneh calls this state of political evolution normal democracy. Assuming that power is a function of merit, the role of socioeconomic development (wealth and education) does not bring power parity among individuals per se, but erases the power bias (the skewed distribution of power) that has been created mainly by autocratic systems.

Some scholars may disagree with aspects of Tiruneh’s theory of political power. For instance, they may conceive power as a static, rather than dynamic, concept. Or they may, on philosophical or moral grounds, contend that citizens ought, regardless of levels of income and rationality, possess an equal distribution of power. The validity of these contentions is unclear. Until a majority of scholars agree on a definition of political power, an understanding of the concept remains incomplete.

**POWER ELITE**

In his 1956 work of the same name, American sociologist C. Wright Mills coined the term *power elite* to characterize a new coalition of ruling groups that rose to dominance in the post-World War II United States. Mills rejected the conventional view of a dispersed, plural, and democratic organization of power and instead saw an increasing concentration of that power in the hands of the three institutional orders that composed the power elite: the military, large corporations, and government leaders. This concentration of power was progressively more centralized and undemocratic. Public discussion and debate over policy was replaced by elite command and control. Mills argued that “within American society, major national power now resides in the socioeconomic, political and the military domains” (Mills 2000, p. 6); the family, religious, or educational arenas, dominant in other eras, have become subordinated to the governmental-military-industrial complex.

Much like the Frankfurt school, Mills synthesized the perspectives of Karl Marx and Max Weber. Advanced capitalist societies were characterized by increasing instrumental rationalization. Following from the dominance of means-ends and strategic rationality, bureaucratic and technological elements became the central structuring factors of social order. Political authority and social power required command and control over technologies, industrial production, the military, and in another sense the higher levels of government. Thus the new power elite derived its position from the concentration of power in large corporations and oligopolies that dominated sectors of industries, and in a strata of political leaders who directed an expanded federal state, as well as a military that dwarfed most other nations in size and had become the largest expenditure in the federal budget.

While the image of a society of small landowners with few sources of concentrated power may have been idealized, it contained an element of truth. By the end of the nineteenth century, however, the United States had become more urban and industrialized. With industrial capitalism came greater concentration of power in the large industries that dominated in the mid to late-twentieth century.

Mills opposed the pluralist school whose foremost representative was political scientist Robert Dahl. Pluralists argued that there were many centers of power in the United States, multiple interest groups that were each capable of setting agendas and checking other powerful groups through veto. Mills believed that the pluralist view was wrong. Power in the United States was highly concentrated and, in most respects, undemocratic. Only the power elite really set the agenda. The notion of a vital political public in which important issues are discussed (an idea central to John Dewey [1859–1952], another important influence on Mills) was descriptively untrue. National government was characterized by an increasing concentration of executive power and a diminution of legislative power. The pluralist outlook mistook mid-level debates on power, which may have had a plural character, for the major centers of power.

Social and political power was concentrated in a small group of interlocking elites who shared a common social world. While members of the power elite did not necessarily possess a unified class consciousness, they traveled in common social circles, followed common career paths, and formed interlocking groups.

Mills agreed with mass society theorists that the displacement of public discussion made way for the influencing, directing, and manipulating of public opinion through new media of communication. The power elites gained control of mass media but also were surrounded by a culture of celebrity in which they participated. The elites not only associated with entertainment celebrities, drawing on their cultural capital, they became celebrities themselves.

Mills’s synthesis of Marx and Weber was not doctrinaire. Mills did not conceive of the power elite as *class* in Marx’s sense. The three institutional orders were not united by a common relation to production, class con-
Power Politics

A consciousness, or simple economic interests. They constituted an elite in the sense used by Vilfredo Pareto (1843-1923) or Gaetano Mosca (1858-1941). They formed an alliance for ruling groups with interlocking membership and sociality. This alliance can shift over time and circumstance.

Mills's conception of the power elite was a major influence on the New Left, especially on its non-dogmatic appropriation of Marx and the radical tradition. It also initiated a major body of research on power structure that further challenged the pluralist argument. The most well-known proponent of power structure research is G. William Domhoff, who continued Mills's research into the social construction of elites in U.S. society.

Critics have noted that Mills may have overstated the permanent role of the military in influencing U.S. society and in forming the power elite. They point out that the nature of leading companies and industrial elite has changed rather radically since the 1960s. Still recent research on the concentration of wealth and power in the United States, such as that conducted by Kevin Phillips (2003), seems to lend support to Mills's concerns.

PRACTICE THEORY

Practice theory is generally recognized as a way to account for social life through the synthesis of societal structures and a person's individual dispositions. Pierre Bourdieu (1930–2002) is perhaps the most famous social theorist associated with this method of apprehending social life—a method that in the early 1990s he termed genetic structuralism. Until his death in 2002, Bourdieu held the chair of sociology at the Collège de France and directed the Centre de Sociologie Européenne.

In Outline of a Theory of Practice (1972), Bourdieu argued that in their attempt to account for social practice, sociologists and ethnographers must not only leave the objectivist grand theories of history and society behind, they must also abandon the unmediated subjectivism of phenomenology and existentialism. For Bourdieu, neither set of theoretical apparatuses could satisfactorily account for the social practice of everyday life. By reconstructing the dialectic between structure and agency, he hoped to reconcile the levels of abstract structures with the actions, feelings, and mental states of individual persons. It is critical to appreciate that while Bourdieu's work is situated in the ethnographic present, it works simultaneously in the world of politics and semantics of institutions, social structures, and social movements.

While Bourdieu vigorously critiqued earlier attempts to theorize social life, he also took seminal aspects of his own argument from European social theorists such as Max Weber (1864–1920), Karl Marx (1818–1883), Ludwig Wittgenstein (1889–1951), Georges Canguilhem (1904–1995), and Georges Bataille (1897–1962). In particular, his use of the concepts of domination, social class, and power reflects earlier economic and sociological theories, particularly those of Marx. In his use of personal dispositions and dynamic personal agency, Bourdieu's work reflects his rejection of Claude Lévi-Strauss's structural anthropology, which in the late 1950s and 1960s had argued that there were specific rules that governed kinship and symbolic structures in traditional society.

Instead, Bourdieu argued for an active synthesis of theory and method as tools to investigate the interactions between larger, objective structures of society and the individual. The thread that connects activism with his method is his understanding of society as a struggle of symbolic and material forces, in which the “truth” about reality is constructed both from interpretation and from structural necessity imposed by a dominant symbolic
structure, which treats its particular version of reality as natural.

In order to achieve adequate analysis, he proposed a set of concepts, defined in such a way that they can be used in any ethnographic situation for the study of everyday life; in fact, it is the empirical work that actualizes this program. Bourdieu also argued that these concepts not only constitute his method of investigating social practice, they imply a theory of social structure as well. Bourdieu’s basic outline for a theory of practice involves three major conceptual categories—habitus, field, and capital—as well as concepts of struggle and strategy, which evoke intentionality on the part of individuals, families, and social groups as they seek to manipulate their position in various social fields.

In brief, habitus refers to durable dispositions, to a sense of one’s place in the social world, and it embodies our understanding of the logic of society and the place we have in it. In broader terms, it refers to social structures that operate on the person, as well as a system of models of perception and appreciation that results from our learning in the world and from our acting in the world.

Bourdieu’s concept of field is one that reflects the space of social interaction, conflict, and competition. Fields are defined by a system of objective relations of power that lie between positions in the field. For Bourdieu, society is a system of fields that are relatively autonomous, but that nonetheless exist in relationship to one another and that collectively exist within a larger social space (defined as the overall conception of the social world). Each field is dynamic and has its own logic and its own structure and forces, which are organized around specific capitals over which individuals and groups struggle as they attempt to maintain or change their position in a field.

In using the concept of capital, Bourdieu rejects the purely economistic meaning of the word, and adds to it the notions of symbolic and cultural capital as ways through which class positions and power are manifested. Broadly defined, capital is a socially valued good. Symbolic capital is the most critical form of capital; Bourdieu argues that not only are precapitalist and capitalist societies organized around symbolic capital, but that capital also structures our everyday lives through the use of judgments about taste, social hierarchy, and methods of discernment. Symbolic capital is also closely connected to class privilege, and the domination of masculine ideology, which is itself related to his use of symbolic violence.

Bourdieu’s work has influenced the fields of sociology, philosophy, education, and social anthropology. In particular, his work has been central in what has been called the reproduction debate, in which scholars investigate the reproduction of social hierarchy and the cultural production of forms of resistance, social identity, and ethnocity. In addition, his has been a voice in the debate on practices of authorship, reflexivity, and objectivity. Perhaps most importantly, Bourdieu has been a political voice that spoke for the dispossessed, the unheard, and those who suffered through the institutions of racism and sexism.

**PRAGMATISM**

Pragmatism refers to the philosophical position that the test of an idea’s truth is its practical consequences. Pragmatism is a reaction against abstract, romantic, and idealistic philosophies, countering instead that the truth of an idea arises from observing its consequences.

Pragmatism was in many ways a product of its era. Pragmatism’s roots are in empiricism and the scientific method, and the energies and enthusiasm of late nineteenth-century American life are obvious in pragmatism. After the Civil War (1861–1865), the United States was exploding with advances in communications, transportation, and technology resulting in scientific breakthroughs and technical innovations such as immunizations, the
telephone, the mechanization of industry, and the like. Thus, American pragmatism—focused on experience and consequences—was extremely different from the romanticism and idealism of much of contemporaneous European philosophy and the arts.

Pragmatism developed in discussions of the Metaphysical Club, a group of faculty and professionals meeting to discuss the issues of the day at Harvard University during the 1870s. Members of the club included the scientist Charles Sanders Peirce (1839–1914), the mathematician Chauncey Wright (1830–1875), the historian John Fiske (1842–1901), the psychologist William James (1842–1910), and lawyers such as Oliver Wendell Holmes (1841–1935), Joseph B. Warner (1848–1923), and Nicholas St. John Green (1830–1876).

Trained as a mathematician and physicist, Peirce is hailed as the father of pragmatism. He first used the term pragmatism in an 1878 article in Popular Science Monthly titled “How to Make Our Ideas Clear.” Peirce’s famous guide was, “Consider what effects which might conceivably have practical bearings we consider the object of our conception to have. Then our conception of these effects is the whole of our conception of the object” (Peirce 1878, p. 24). Peirce, who later renamed his pragmatism pragmaticism, argued that it was a powerful empirical and philosophical tool because it demanded that ideas be examined for their consequences, not for the elegance of some abstract metaphysical model. He wrote about pragmatism:

It will serve to show that almost every proposition of ontological metaphysics is either meaningless gibberish—one word being defined by other words, and they by still others, without any real conception ever being reached—or else is downright absurd; so that all such rubbish being swept away, what will remain of philosophy will be a series of problems capable of investigation by the observational methods of the true sciences. (Peirce 1905, p. 171)

WILLIAM JAMES AND JOHN DEWEY

Certainly the best-known proponent of pragmatism was William James. Trained in medicine, he spent most of his adult life studying and teaching the new field of psychology at Harvard University. James popularized pragmatism, giving Peirce credit for its founding in a 1908 address at the University of California. In his chosen profession of psychology, James is famous for his notion of “stream of consciousness.” The term is much misused today, but for James it meant that the mind is active in giving meaning to experiences that it encounters. James’s pragmatism is rooted in his understanding of psychology. James argued that the “truth” of ideas lay not in their abstract formulation but in their “cash value” as consequences in human experience. He wrote: “The whole function of philosophy ought to be to find out what definite difference it will make to you and me, at definite instants of our lives, if this world-formula or that world-formula be the true one” (James [1907] 1986, p. 50).

James applied his theories to a number of philosophical areas, including the question of religion and the supernatural. In his famous works The Will to Believe (1897) and The Varieties of Religious Experience (1902), James explored the power of the individual “will to believe.” James concluded that although the materialist might wrongly conclude that religion was a fallacy, the positive effects on the life of the individual adherent (rather than the existence of God) demonstrate the “truth” of religion. He wrote: “On Pragmatic principles, if the hypothesis of God works satisfactorily in the widest sense of the word, it is true” (James [1902] 2002, p. 299).

James’s contemporary, John Dewey (1859–1952), chair of the philosophy department at the University of Chicago at the turn of the century, is best known for his work on education and social issues. Dewey’s guiding philosophy, instrumentalism, is a strand of pragmatism. Dewey was critical of abstract and theological notions of truth and reality. He defined his instrumentalism as “an attempt to constitute a precise logical theory of concepts, judgments, and inferences in their various forms, by primarily considering how thought functions in the experimental determinations of future consequences” (Dewey 1903, p. 21). Dewey’s approach utilized a praxis formula for inquiry as the method for advancing knowledge. Dewey believed that through experience the mind acquires knowledge, but over time new experiences challenge the previously held beliefs. The process of inquiry, challenging staid ideas and the resulting new synthesis, is the process by which truth becomes known to the individual.

Pragmatism was applied to law by members of the Metaphysical Club, including Supreme Court justice Oliver Wendell Holmes Jr. and Nicholas St. John Green. Holmes argued that the law should be interpreted not on static historical observation of the original intent of the framers of the constitution but by considering the practical outcomes of the law or judgment in question. In other words, the cardinal rule of jurists should be the practical policy consequences of a given outcome in their deliberation. Holmes recognized that such a view of the judiciary empowers it with a dynamic and legislative function akin to that of the Congress. This practical approach to the outcomes of the law, in distinction to theories of law rooted in tradition, religion, and metaphysics, is shared among legal pragmatists.
THE PHILOSOPHY OF PRAGMATISM

In philosophical terms, pragmatism is generally considered to be nominalistic and pluralistic. Ideas are not “real” as abstract, formal categories, but change as experiences are apprehended and given meaning by the mind. The philosopher Ferdinand C. Schiller (1864–1937) wrote: “Concepts are tools slowly fashioned by the practical intelligence for the mastery of experience” (Schiller 1907, p. 64). Thus, for Schiller there is no single Truth, although there are truths that are relevant within a given context. James agreed, citing that truth was not static but “ambulatory,” directly related to human experiences. Moreover, old “truths” may no longer be relevant to the contemporary setting because they no longer adequately convey meaning about the world as it is. Thus, they are no longer true.

For pragmatists, ideas are contextual and their worth derives from the utility of their consequences. This epistemology is rooted in a rejection of Western teleology and monism. For the pragmatist, there is no first cause, nor is there a single ultimate end. Rather, the world is pluralistic in that social and empirical phenomena are connected but it is the individual who gives meaning to experience, and therefore the value of a concept is in its practical consequences. James wrote: “The distinctions between thoughts and things ... the conceptions of classes with subclasses within them ... surely all these were once definite conquests made at historic dates by our ancestors in their attempts to get the chaos of their crude individual experiences into a more shareable and manageable shape” (James 1909, p. 62).

Although not exclusively an American philosophical tradition, pragmatism is usually identified with Americans such as Peirce, Holmes, Dewey, Wright, Schiller, and especially William James. However, pragmatism crossed the ocean, influencing and being influenced by others, such as the Italian authors Giovanni Papini (1881–1956) and Luigi Pirandello (1867–1936) and the French philosopher Henri Bergson (1859–1941). Other well-known pragmatists included George Herbert Mead (1863–1931), James Hayden Tufts (1862–1942), and Sidney Hook (1902–1989). Many of the assumptions of pragmatism were to influence later twentieth-century philosophical currents, particularly that of secular humanism.

PRAXIS

“Praxis,” from the Latin, is the opposite of “theory.” The Greek praxis and its related stem, “prassein,” means “to do.” It is commonly defined as “action” or “practice.” Traditionally, there has been a perceived dichotomy between theory (speculation, thinking) and praxis (action, doing). However, contemporary notions of praxis, especially as the Marxists see it, reject this distinction.

There are two prevalent meanings of praxis in the modern day: one in religion and ethics, and one in social theory and political philosophy. In Catholicism, praxis refers to applying the principles and ethics drawn from religion to everyday life. It is, in a sense, applied belief. The idea is that the practice of one’s religious beliefs enables one to live a just life. Hence, belief (theory) leads to a just society.

In *Phenomenology of Spirit*, German philosopher Georg Wilhelm Friedrich Hegel (1770–1831) argued for the interrelationship of thought and action, linking theory and praxis. Karl Marx (1818–1883), in a movement against idealism and metaphysics, proposed a “practical-critical” activity that combines theory with practice, where no thinking can be isolated from social practice (Marx 1845). This linkage of thinking with action marks the most sustained examination of the question of praxis in contemporary critical theory (CT).

Praxis is given a specific agenda and political program in the Frankfurt School’s CT. CT erases the distinction
between theory and praxis by showing how one leads to and informs the other. Praxis is theory that serves the purpose of social transformation. The social transformation sought by praxis is not only informed by critical reflection (“theory”) but also by questions of justice and emancipation (social or collective action). It corresponds therefore to Marx’s “practical-critical” thought.

“Theory” in CT is essentially a question about reflection as related to knowledge. As philosopher Max Horkheimer (1895–1973) understood it, CT is a form of knowledge distinguished not just by its specific object of knowledge but also by its special relation to this object. Knowledge or theory is directed at society and social relations (its object). The relation is not one of mere “interpretation” or “analysis” of this object-society. The relation to this object of study (society) is informed by the aim of emancipation. Theory is thus directed at a goal: a just society. Knowledge leads to, or at least aims for, social justice. In this sense CT is not independent of political action or program. This Marxist line, as Horkheimer elaborated, sees theory as “an element in action leading to new social forms” (Critical Theory 1972, p. 216). This emphasis on action and superior knowledge distinguishes it from traditional theory where the object of knowledge and the subject are in a passive relation. In CT, reflective theory engages with the object in such a way as to transform both itself and the object.

CT is here a program of social research, investigating social conditions of facts as well as of theory. It resists the institutional demarcation of theory and application. The philosophical (theory) and the social (praxis) come together in this formulation. It applies thought to the entirety of human existence.

CT’s mode of engagement with the social can be described as “knowledge as action.” It calls for active thought that continually challenges the existing state of affairs in society. The praxis of CT is in its thinking differently about the social world, where a different thinking will lead to changes in the way life is lived. CT does not offer a program of change in material experience; it offers a mode of understanding that can transform how material experience in modernity is interpreted. In CT a critique of culture may bring about changes in society because it develops new frames for interpretation, knowledge, and action.

Feminist exponents of critical ethnography express these elements most strongly in making praxis the defining moment of all investigative methodology. Such an ethnography focuses on political practice and breaks down the gap between researcher and object of research. Others, such as the education and cultural studies scholar Handel Kashope Wright, see the discipline of cultural studies as “social justice praxis work” where interpretation, or theory, must be informed by a commitment to social justice. Thus, praxis is political action informed by knowledge, where knowledge itself is driven by self-reflection and the need to engage with goals of justice and emancipation.

PREBISCH, RAÚL

1901–1986

Raúl Prebisch was a highly influential Argentinian economist and policymaker of the twentieth century. He is best known for proposing the idea that the world economic system consists of two connected elements—an industrialized center and an underdeveloped periphery—wherein the former dominates the latter. Contrary to the Ricardian claim that trade benefits all, Prebisch argued that trade between the center and periphery is unequal and detrimental for the periphery, and that became increasingly true as the world economy developed. His ideas were central to Latin American structuralist and dependency schools of thought. During the middle decades of the twentieth century, they led to the widespread adoption, in the periphery, of import substitution industrialization (ISI) policies that focused on “inward-directed” industrial development.

Prebisch’s ideas achieved a wide dissemination and receptivity when he headed the United Nations (UN) Economic Commission for Latin America (ECLA) between 1948 and 1963. One of his central theses was that, in the long run, primary producers in the periphery faced declining terms of trade for their exports vis-à-vis manufactured goods. This view received empirical support from a 1949 UN study, *Relative Prices of Exports and Imports of Underdeveloped Countries*, which examined the
period between the late nineteenth century and end of World War II. Prebisch and the ECLA pointed out that during the upswing of a trade cycle, prices of primary goods rise faster than those of industrial goods, but that they fall much more steeply during the downswing, causing an overall decline in prices by the end of the cycle. In the industrialized center, the strength of organized workers and firms causes a relatively smaller decline in the prices of industrial goods during a downswing, while the vulnerability of farmers and unorganized workers leads to sharp declines in prices in the periphery.

Prebisch's ideas were shaped by the experience of Argentina in its trade with industrialized nations such as Great Britain and the United States, both before and after the Great Depression. Another UN economist, Hans Singer, argued that income elasticity of demand for industrial goods (percentage increase in the demand for industrial goods associated with a percentage point increase in people's incomes) is higher than that for primary goods, thereby causing a decline in the benefits from trade for the periphery over the long run. Together, these ideas came to be known as the Prebisch-Singer hypothesis.

Prebisch's work has predictably attracted criticism from mainstream trade theorists. While the UN report that originally provided the empirical basis for Prebisch's theory has been largely discredited, later studies have supported the Prebisch-Singer hypothesis. International Statistics Institute (ISI) policies have been blamed for certain longstanding problems, such as unsustainable debt levels in the periphery. Notwithstanding such critiques, ISI policies have also led to substantial increases in income and the development of an industrial base in a number of developing countries.

Prebisch's insights remain important today for regions and countries in the periphery, notably Africa. Scholars continue to argue in favor of careful, “inward-directed” policies with concerted cooperation among countries in the periphery, and for the establishment of multilateral institutions that genuinely represent their interests. This vision informed the founding (in 1964) of the United Nations Conference on Trade and Development (UNCTAD), a multilateral organization that Prebisch headed for its first six years. If there was ever a need for such institutions to represent the interests of the periphery on the world stage, it is at the present critical juncture of global integration. Indeed, there is a strong and growing literature among critical development scholars on the negative effects of globalizing policies for developing countries. These scholars are arguing that existing multilateral organizations such as International Monetary Fund or World Trade Organization have not represented the interests of the periphery adequately.

PREBISCH-SINGER HYPOTHESIS

The classical economists believed that the terms-of-trade of primary products would show long-term improvement vis-à-vis manufactures due to the operation of the law of diminishing returns in primary production and the law of increasing returns in manufactures. The policy implication of this classical proposition is that a primary-producing country need not industrialize to enjoy the gains from technical progress taking place in manufactures; free play of international market forces will distribute the gains from the industrial countries to the primary-producing countries through the higher prices of their exports of primary products relative to the prices of their imports of manufactures (that is, the terms-of-trade will move in favor of primary-product exporting countries).

THE PREBISCH-SINGER HYPOTHESIS AND ITS POLICY IMPLICATIONS

The opposite hypothesis—the Prebisch-Singer hypothesis of long-term deterioration in the terms-of-trade of primary products—can be traced back to the early mid-twentieth-century writings of Charles Kindleberger. He thought it inexorable for the terms-of-trade to turn against primary producing countries because of the operation of Engel’s law—which states the demand for goods needed for bare subsistence such as food rises less than...
proportionately while demand for other luxury consumption goods rises more than proportionately—in the process of world economic growth and improvements in the standard of living. It was, however, a 1945 League of Nations report prepared by Folke Hilgerdt and its subsequent follow-up by the United Nations in 1949 that is actually the origin of the Prebisch-Singer hypothesis and the related debate. It was observed in these reports that during the sixty years preceding 1938 primary product prices had fallen relative to prices of manufactures.

In the 1950s both Raúl Prebisch and Hans Singer referred to this so-called historical fact and questioned the classical proposition and its implicit support for the colonial pattern of trade. It was pointed out that productivity increased faster in the industrialized countries (constituting the North or the industrial center) than in the primary-producing countries (constituting the South or the raw-material supplying periphery), so that the terms-of-trade should have moved in favor of the South, given the factors of free trade and competition. The South could have enjoyed the fruits of technical progress taking place in industry through free trade and specialization (in primary production) without going for industrialization, as suggested in the classical writings. But this did not happen as the available evidence showed. So the primary-producing countries were advised to pursue a vigorous policy of industrialization with the suspension of the free play of international market forces.

THE EVOLUTION OF THE PREBISCH-SINGER HYPOTHESIS

In the post–World War II period, the Prebisch–Singer hypothesis provided the theoretical basis for the policy makers of the newly independent countries to adopt a path of import-substituting industrialization (ISI) through protective commercial policy. The path of ISI in basically agricultural countries required imports of machines and technology. So, in the process of industrialization these countries began to face acute balance-of-payments problems. This led many southern countries to follow the path of export-oriented industrialization. Dependence on a few primary-product exports was reduced and these began to be substituted by manufactured exports.

Meanwhile, the emphasis of the Prebisch–Singer hypothesis shifted from the relations between types of commodities to relations between types of countries. The shift of emphasis too had its origin in the writings of Kindleberger in the mid- to late 1950s. He found no conclusive evidence of deterioration in the terms-of-trade of primary products, but he did have some evidence of a decline in the terms-of-trade of the primary-producing countries (South) vis-à-vis the industrialized countries (North). In fact, both Prebisch and Singer had in mind the concept of terms-of-trade between the North and the South. But, in the absence of appropriate data, they used the series on terms-of-trade between primary products and manufactures as a proxy, with the logic that primary products dominated the then export structure of the South and manufactures dominated that of the North.

The Prebisch-Singer hypothesis generated much controversy in the academic world. In their published papers, critics such as Jacob Viner (1953), R. E. Baldwin (1955), G. M. Meier (1958), G. Haberler (1961), R. E. Lipsy (1963), Harry Johnson (1967), Paulairoch (1975), Ronald Findlay (1981), and many others raised different statistical questions and discarded the hypothesis. Since the 1980s, a series of studies undertaken by John Spraos (1980), David Sapsford (1985), Prabirjit Sarkar (1986a, b, 1994, 2005), Sarkar and Singer (1991), E. R. Grilli, and M.C. Yang (1988), and many others questioned the validity of the criticism and provided strong statistical support for the Prebisch–Singer hypothesis, thereby bringing it back into the limelight.

THE PREBISCH-SINGER HYPOTHESIS: DIFFERENT EXPLANATIONS

The question that logically follows is what explains the deteriorating trends in the terms-of-trade of the South? The factor highlighted by Singer is the raw-material saving and/or substituting technical progress in the North which created a demand bias against southern exports in the process of growth of northern manufactures leading to a fall in the southern terms-of-trade.

In his 1950 work Prebisch tried to explain the phenomenon in terms of the interaction of the diverse economic structures of the North and the South with different phases of business cycles. In an upswing, wages and profit, and so prices, rise more in the North than in the South due to stronger labor unions and higher monopoly power of the northern capitalists. In the downswing, northern profits and wages do not fall much due to the same reason. The burden of adjustment falls on the raw material suppliers of the South; their prices fall more than the prices of manufactures.

The diverse economic structures created an asymmetry in the mechanism of distribution of the fruits of technical progress, argued Prebisch, Singer, and Arthur Lewis in their individual works published in the 1950s. In the North, technical progress and productivity improvements led to higher wages and profit while in the South, these led to lower prices. The North-South models of Findlay (1980) and Sarkar (1997 and 2001b) supported this asymmetry. Granted this asymmetry, the terms-of-trade would turn against the interest of the South in the process.
of long-term growth and technical progress in both the North and the South.

In 1997 Sarkar provided another explanation in terms of product cycles. A new product is often introduced in the North. Initially there is a craze for this product and its income elasticity is very high. Owing to a lack of knowledge of its production technique, the South cannot start its production. The South produces comparatively older goods with lower income elasticity. By the time the South acquires the knowledge, the North has introduced another new product. In such a product cycle scenario, the income elasticity of southern demand for northern goods is likely to be higher than that of the northern demand for southern goods. Under these circumstances, if both the North and the South grow at the same rate (or the South tries to catch up by pressing for a higher rate of growth), the global macro balance requires a steady deterioration in the terms-of-trade of the South vis-à-vis the North.

Many other theoretical models exist to explain the Prebisch-Singer hypothesis. As it is increasingly recognized to be a fact, not a myth, many other models will be forthcoming.

PRE-COLUMBIAN PEOPLES

The term pre-Columbian refers to the time before Columbus first set foot in the Americas. He sailed to find alternative routes to the East, as Asian imports had become very expensive in Europe after the Turks conquered Constantinople in 1453. Yet pre-Columbian peoples had flourishing civilizations long before the arrival of Columbus. Each society had prescribed laws and unique religions, and far from the savage cultures that history painted them to be, several societies were highly sophisticated.

Some scholars have postulated that around the time that the Israelites chose David as their king, a tribe of Asians crossed the land bridge that became the Bering Strait in search of new game. These people, called the Nadene, closely resembled modern Mongolians. About two thousand years ago, the group split into two factions—the Tlingit and Haida tribes, which went to the northwestern coast of North America—and the Athabascans, who stayed in Alaska around Lake Athabasca. But the Athabascans continued to move southward to form tribes in the Southwest.

Although this scenario is speculation, many similarities exist between the Asian peoples and Native American tribes. For instance, the mandala of the Hindus and Buddhists closely resembles the sand paintings of southwestern tribes. Early Asian calendars were also similar to those of the Aztecs. Special significance was often placed on the number four. Although no physical proof of this migration exists, signs point to its possibility. Asian tribes may have migrated as far south as the tip of South America.

One of the oldest tribes on record lived in the Four Corners area of the southwestern United States. They were called the Pueblos, and their ancestors were the Anasazi, a tribe that existed two thousand years ago. The Anasazi are known for their elaborate apartment buildings, built on the sides of cliffs. Later, the Pueblos used adobe and wood to build their homes. Their hunter-gatherer status changed around the year 1000 BCE, when they began to plant corn, squash, and beans, and to craft fine pottery.

The people who lived in Cahokia, in what is now southwestern Illinois, are known popularly as the “mound builders” because they built large structures for underground burial, governmental, or ceremonial purposes. The society is thought to have been territorial, led by a chieftain, and possessed the most elaborate hierarchical system in its time.

In Mesoamerica, as each new culture appeared, it adapted, and often improved upon, significant elements of the civilization that had come before. The Olmecs, the original civilization, lived in wood and thatch huts in a humid area on the Gulf Coast of Mexico. They raised corn, beans, and squash, worked with fine stones, and made pottery. It is theorized that the Olmecs traveled and traded throughout the area and thereby spread their culture throughout the region.

The Zapotec capital, Monte Alban, began to flourish at about the same time as the Olmec society fell into decline. The Zapotecs may have built the first observatory, and their system of glyph writing was the first writing of any type to be used in Mesoamerica. They recorded the first calendar, although the Olmecs may have begun to develop a similar system of counting the days before them.

The Mixtecs seem to have taken over sites where Zapotecan society was failing. The Mixtecs were exquisite goldsmiths, but their most significant contribution is the written record of their history, which covered a period of almost 600 years beginning around 940 CE.

Thriving at roughly the same time was another people, whose true name is still unknown. The name Teotihuacanos comes from their city—Teotihuacán, named by the Aztecs long after the civilization fell. Although few written records exist, a glimpse of their culture survives in colorful frescoes, which adorn palace walls. It appears that the Teotihuacanos traded goods widely, had a class-based society with specialized jobs, and worshipped a number of gods. They were also weavers and potters and jewelers who worked in semiprecious stones. Their civilization sharply declined around 700 CE, when the city was sacked and burned, probably by barbarian tribes from the north.
The Mayan society, which first appeared around 1000 BCE, was prevalent in parts of Mexico and farther south into Central America. They refined the art of writing and the calendar to their highest forms up until that time. Mayan art developed between about 200 and 900 and is considered to be the most sophisticated and beautiful of the region. The Mayans are known for their mathematical prowess and traded in salt, cacao, and obsidian.

No society in ancient Mesoamerica was as revered as the Toltecs. Later societies credited the Toltecs with inventing astronomy, the calendar, and the arts because of the finely crafted items found in the ruined Toltec capital of Tolan; however, historical fact disproved these claims. Toltec civilization fell into decline after Tolan was burned and sacked around the year 1150, and after the city vanished, an even more sophisticated and powerful people came to revere them. They adopted Toltec music, called their artists “Totecats,” and copied Toltec artistry in sculpture, architecture, and featherwork. They even proudly claimed Toltec lineage. These people called themselves the Mexica (me-SHI-ca), but history knows them as the Aztecs.

The Aztecs were arguably the most advanced culture to have arisen in pre-Columbian times, although they are more often remembered for their ritual practice of human sacrifice. Yet the Aztecs had a well-developed military, and they enlarged their capital of Tenochtitlán, now Mexico City, through the construction of floating farm plots known as chinampas. The Aztec pantheon was elaborate, their educational system substantial, and they held great esteem for the arts.

Farther into South America were the Incas, whose society developed only shortly before the arrival of Columbus in the New World. Still, they managed to expand their influence throughout western South America by the time of their demise in 1533. The Incas are most remembered for their architectural construction, such as that at the site of Machu Pichu.

In the Bahamas and the Greater Antilles Islands, which include Cuba, Puerto Rico, Haiti, the Dominican Republic, and Jamaica, the Taino culture was the dominant society before the time of Columbus, although Ciboney and Guanahtabey (western Cuba), Macorix and/or Ciguayo (Bohio), and even Carib (Lesser Antilles) were also present. They were united by Arawak, the common language. As they were island cultures, they were adept sailors, and fishing was their main occupation, but the islands also provided abundant edible fruits and they used the fauna of the land to fulfill their needs. In 1492, the Taino had a thriving civilization. As the Mesoamerican cultures had, they constructed ceremonial ballparks, and they had an elaborate hierarchy of gods. They lived in five predominant kingdoms on Hispaniola, which were led by chieftains to whom tribute was paid. They raised crops of casaba melons, garlic, potatoes, and other fruits and vegetables, with yucca being their staple food. They had no system of writing nor a calendar, and could count only up to twenty using their hands and feet. But the Taino made exquisite handcrafted works, with pottery being the most remarkable.

Other less political societies also existed in North America before the arrival of Columbus. They were independent city-states, thriving in small groups. Their less-centralized chieftom polities were also evident and included a central community surrounded by bordering neighbor villages. Each community had a central ruler, with a subservient underclass. When Columbus landed in the Bahamas, he was the first European to encounter the Taino. He called them “Indians” because he thought they had landed in India, and the appellation became the common term to describe all Native American peoples in the Americas.

Population estimates of pre-Columbian peoples in North America range from 8 million to more than 100 million, centered mainly in Mesoamerica and South America. However, because of incomplete evidence, the true population is difficult to determine.

PREDATOR-PREY MODELS
SEE Predatory Pricing.

PREDATORY PRICING
Predatory pricing is primarily a strategy of price reduction that intends to eliminate a rival firm and thus increase market power. More generally, the goal of predatory pricing may be to discipline or otherwise inhibit a competitor. Also, while price is typically the instrument used for this purpose, other actions may be taken, such as bundling, refusing to supply, or other practices that effectively raise the rival’s cost of doing business. Predatory pricing is therefore just one form of predation—though arguably the most commonly practiced and studied.

Predatory pricing is a controversial issue in scholarly and legal circles alike. On one hand, price cuts can be used as a means to exclude rival firms and increase future market power. On the other, price cuts are the bread and butter of market competition. Thus it is very difficult to distinguish genuine competitive pricing from predatory (and thus anticompetitive) pricing; and even if predatory pricing has negative long run effects, in the short run it has the same positive effects of aggressive competitive pricing.

LEGAL PERSPECTIVES
Allegations of predatory behavior are as old as oligopoly competition. Starting in the nineteenth century, examples include ocean shipping, sugar, tobacco, oil, and others. For example, some historians argue that, in the late 1900s the Southern Bell Telephone Company effectively eliminated competition through a strategy of pricing below cost in response to entry.

Reviewing the evidence in one of the most prominent cases, Standard Oil Company of New Jersey v. United States 221 U.S. 1 (1911), economist John McGee argued that there is little support for the allegations of predatory behavior. More importantly, he argued that the concept of predatory pricing itself lacks logical consistency. Of the several reasons pointed out by McGee, one deserves special attention. McGee maintained that, in addition to the prey, the predator too suffers from predatory pricing. If the prey resists predation and remains active, then the predator eventually will give up its efforts. Anticipating this outcome, the prey is indeed better off resisting predatory efforts. Anticipating this outcome, in turn, the alleged predator is better off refraining from its predatory strategy. Even if the alleged prey were short of cash, it could always borrow from a bank with the (correct) promise that its losses are only temporary. One can hardly underestimate the influence of McGee’s work, both in economics scholarship and in legal practice.

Early-twenty-first-century legal rulings in the United States illustrate a skeptical approach to the concept of predatory pricing. This is particularly apparent in two important decisions by the U.S. Supreme Court: Matsushita Electric Industrial Co., Ltd. v. Zenith Radio Corp., 475 U.S. 574 (1986) and Brooke Group Ltd. v. Brown & Williamson Tobacco Corp., 509 U.S. 209 (1993). Adopting the theories of McGee and his followers, the Court embraced the view that predatory pricing schemes are rarely attempted; and that, if attempted, their success is rare.

In contrast to the United States, the European Union’s (EU) approach to predatory pricing (based on Article 82 of the European Community Treaty) is rather aggressive. For example, in 2003 France Telecom SA was fined for “offering its services at a loss” in the high-speed internet access market.

Broadly speaking, the U.S. and EU approaches to testing for predatory behavior are similar: They look for evidence that there is (a) a sacrifice of short-term profits; and (b) a reasonable expectation that such losses are compensated by long-term gains from greater market power. The main difference between the United States and Europe is the strength of the second requirement, which is weaker in Europe. (There is also some divergence with respect to part (a). Typically, evidence of short-term losses is gathered by comparing price to some measure of cost. The question is then what measure of cost makes the most theoretical and practical sense.)

ECOmatic PERSPECTIVE
For a long time, McGee’s analysis provided the only coherent economic theory of predatory pricing. But unlike legal practice, economic thinking has departed significantly from McGee’s theory. The research suggests that there are several reasons why predatory pricing is a plausible strategy. One reason is asymmetry of information between predator and prey. By repeatedly fighting rivals with low prices, a predator increases its reputation for toughness; and thus encourages exit and discourages future entry. Alternatively, if the prey is uncertain about the predator’s costs, then the latter’s low prices signal that the predator’s costs are low too, and so are the prey’s long term prospects.

A related source of information asymmetry is between the prey and capital markets. One of the key points in McGee’s case against predation is that, if the alleged prey were short of cash, banks should be willing to step in with a loan under the (correct) promise that the prey’s losses are only temporary. But due to imperfect monitoring of the borrower’s actions banks are forced to
offer contracts where future financing is contingent on repayment of current loans. In this context, the predator may have an incentive to price below cost: While the predator loses money, so does the prey; and to the extent that lower current profitability decreases the probability of loan repayment, the predator has something to gain in the long run—the possibility that the prey, unable to secure financing, will be forced out of the market.

Finally, a third class of equilibrium models of predatory pricing is based on dynamic effects through the firms' profit functions (either through demand or through costs). Consider the case of two competitors moving down the learning curve. If the lagging firm loses the current sale, it might find itself so far behind the race that exit is the best option. Anticipating such behavior, the leader has an incentive to price aggressively, possibly below cost, thus increasing the chances of monopolizing the market. Unlike the previous theories, this one does not rely on asymmetric information between firms or between firms and capital markets. Moreover, while the learning curve provides a natural link between current sales and future profits, there are several other examples: switching costs, installed base or network effects, and so forth.

In summary, although U.S. legal doctrine is rather skeptical with respect to predatory pricing, economic theory has provided a wealth of coherent explanations of why predation is plausible.

PREDICTION

Prediction can be defined as "to declare in advance: foretell on the basis of observation, experience, or scientific reason" (Webster's 7th New Collegiate Dictionary). Predictions can be short-term, long-term, qualitative, quantitative, negative, positive, optimistic, or pessimistic. They can be based on hunches, guesses, folklore, astrology, palm reading, extrapolations from data, or scientific laws and theories or alleged laws of historical change. The term prediction overlaps with prophecy but has somewhat different connotations.

Not until the seventeenth and eighteenth centuries did prediction take on its modern connotations. Pierre-Simon Laplace (1749–1827), arguably its first major theorist, presented a systematic answer to the major theoretical and practical problem prediction raises: Why are we so successful in some areas of research (e.g., astronomy, physics, and chemistry) but conspicuously less successful in others, particularly human behavior? The most frequently given answers are that some phenomena are intrinsically unpredictable, or we are not using correct scientific methods, or the complexity of the phenomena rule it out, or it is due to limits of human ignorance, fallibility, and superstition. The twentieth century saw significant developments in the theory and practice of prediction, with simultaneous significant advances in predictive accuracy and a greater awareness of the limits of such accuracy.

EMPIRICAL AND PRAGMATIC SIGNIFICANCE

There are four major theories concerning the possibility of predictive success in the areas where, so far, they have been rather limited. The first is Laplacian determinism, named for Laplace, who asserted that an intelligence endowed with omniscience (who therefore would know the current position and velocity of all particles, as well as the laws that control their behavior) could predict every future event.

The second view, the covering law model, is based on the two principles involved in the Laplacian view. As developed by Karl Popper (1934), it requires that an adequate explanation be deduced from universal laws and initial conditions (a generalization of Laplace’s positions and velocity). The more general and more precise the prediction, the better it is. This is because it is more testable, which in Popper’s view means “falsifiable.”

The third position, probabilistic prediction, is more modest but still in accordance with Laplace’s view that our ignorance and fallibility forces us to rely on probability, not certainty, in our predictive endeavors. We can predict a 60 percent chance of rain this weekend, but not with the virtual certainty of astronomical predictions (e.g., that Venus will be in transit in 2112) or those based on
(Newtonian) laws of gravity and motion. The quantum physics uncertainty principle is often seen as the paradigm case of this type, although weather predictions and many social phenomena may be better examples, given that quantum electrodynamics has the most numerically precise, accurate predictions in the history of science.

The final theory, *pattern prediction*, originated with Warren Weaver (1894–1978), a natural scientist, but was made widely known to economists and social scientists by Friedrich von Hayek (1899–1992). This position seems furthest from Laplacian determinism. Pattern prediction downplays precise quantitative predictions, and has a weakened type of testability, due to the theory of complex phenomena adapted from Weaver. It appears to harmonize well with modern chaos theory and with probabilistic reasoning about phenomena. However, the most recent developments in the theory and practice of prediction may be making it more susceptible to quantitative precision.

Any adequate theory of prediction should allow retrodiction as a special type. If one predicts that devaluing the currency will lead to inflation, then a study of such policies in ancient Rome, Egypt, or China should find these results. This can be defined as prediction, although it concerns not the society studied but what the scholars of such societies should find.

**CRITICISM OF METHODOLOGY**

B. F. Skinner's behaviorism emphasized prediction and control; his position was extreme Laplacian determinism. The reason for our inability to be as successful at predicting human behavior as we are with predictions made in physics and astronomy is due to our failure to apply proper scientific method, primarily because of a lingering antiempirical belief in an inner man not subject to the laws of nature. But the history of science since Newton has postulated several unobservable entities (e.g., atoms, gravity, natural selection) with spectacular practical and empirical success.

Logical positivism (including Popper's weakened version) associated predictions with testability, meaning both verifiability and falsifiability. But it has been argued on both logical and historical grounds that a false prediction does not always disprove a theory. Nor does verification of predictions prove the theory true for purely logical reasons (the fallacy of affirming the consequent).

Popper that, in contrast to unconditional historical prophecies, scientific predictions are conditional (1963). This is based on his model described above and the laws he argues are conditional not asserting the existence of the initial conditions. But the model only works for systems that are well isolated, stationary, and recurrent (Popper 1963). This is why predictions of eclipses and the regularity of the seasons can be made accurately, because the solar system is such a system. Such systems are not typical; they are special cases where scientific prediction becomes particularly impressive.

In addition, there are arguments based on the nondeterministic character of classical physics. The “three-body problem” undermines Laplacian determinism. The three-body problem arises out of the inability of physics (so far) to use Newton's laws for more than two bodies.

The twentieth-century scientist Edward Lorenz, distinguished between two types of determinism thus: “one with clear rules that apply always and everywhere” so that repetition of the same conditions makes prediction possible and another where “small variations aggregate and amplify” (Kaplan and Kaplan, 2006, p. 221) and so repetition prevents prediction. The former will result in long-run variation canceling out, with a clear pattern emerging. The latter leads to what are now called “chaotic systems,” which are extremely sensitive to initial conditions.

Despite these impediments, progress has been made in improving meteorological and other types of predictions by the use of “ensemble prediction” as well as “threshold” and “pattern effects.” The former involves turning predictability itself into a variable, such as temperature or rainfall. The latter combines Weaver’s pattern prediction with the important idea of threshold effects, as in the second type of determinism described in the preceding paragraph. Threshold effects are best illustrated by the straw that broke the camel’s back.

Developments in the last two decades are improving efforts to predict possible disasters such as earthquakes, tornadoes, epidemics, and perhaps climate change, as well as the interactions of large groups of people, their societal effects, and their impact on the environment. (Cribb, 2006). Great use has been made of modern computers, often employing simulated effects over centuries (which leaves a great margin of error due to unreliable data), possibly unjustified assumptions in constructing the models, and human fallibility, yet there are good indications of improved predictive ability with computers.

Nonetheless, we are nowhere near Laplace’s omniscient intelligence, and for theoretical and practical reasons we are unlikely ever to be. The major reason is that the mathematics and data used are both so complicated (millions and millions of lines in a computer code) that no one person can master it. In addition, it relies on Bayes’ probability theory. The mathematics of that is not very complex, but it requires initial assignments of probability, which can then be modified by new evidence. However, there are numerous problems in deciding how to assign these so that they are not too arbitrary.
Preemptive Strike

The decision to use military force can be made in a variety of different situations and in response to numerous different triggers or actions taken by an enemy or adversary. A preemptive strike is a military action taken to forestall an imminent military attack or other type of threat. This type of activity is different from a preventive action, which is undertaken to counter a more distant threat. In this respect, a preemptive strike deals with a current threat, while preventive action deals with a potential or future threat.

Preemptive strikes are generally motivated by the fear of an impending attack or invasion. In this scenario, the leadership of a state believes its adversary is preparing for an attack or invasion. Instead of waiting for the attack to actually occur, the leadership decides to take action first—to launch a preemptive strike against the adversary.

The Israeli decision to strike against Egyptian forces on June 5, 1967, is an example of a preemptive strike. The Israelis believed that the Egyptians were poised for their own attack and that Israel could ill afford to absorb such an attack. As a result, the Israelis decided to launch a preemptive strike to forestall the imminent Egyptian attack.

A preventive action, on the other hand, would be undertaken to deal with a threat that could develop sometime in the future. With preventive action, the “threat” posed by the target is distant in nature, and in some cases a mere potentiality. The Israeli strike against the Iraqi nuclear reactor at Osiraq in June 1981 is an example of a preventive action. Israel struck the Iraqi facility in order to forestall the further development of the Iraqi nuclear program, which the Israelis viewed as a threat. This action was not really “preemptive” in nature, however, in that Iraq did not pose an imminent threat to Israel.

The distinctions between preemptive and preventive actions are important, but often confused. The 2002 National Security Strategy of the United States of America (NSS) describes a strategy identified as “preemptive,” but in actuality it is closer to being preventive in nature. The NSS states, in the context of the threat from weapons of mass destruction, that “the greater the threat, the greater is the risk of inaction—and the more compelling the case for taking anticipatory action to defend ourselves, even if uncertainty remains as to the time and place of the enemy’s attack” (p. 15). The fact that the NSS stresses that the “time and place” of the attack are unknown makes the policy preventive. However, the NSS goes on to state, “To forestall or prevent such hostile acts by our adversaries, the United States will, if necessary, act preemptively” (p. 15).

While preemptive strikes do involve the “first use of force,” they are generally viewed to be reactive policies, or actions taken in self-defense. Preemptive strikes are usually carried out in response to some action taken by the enemy that is believed to signal preparations for an imminent attack. Preventive actions, on the other hand, are taken in response to activities that could develop into a specific threat at some point in time in the future.

This distinction has important implications, particularly with respect to international law. International law allows for the first-use of force in response to an imminent threat, but not in response to a distant threat. Or, in other words, preemption in response to an actual and imminent threat is OK, but preventive action is not. The line between imminent and distant threats, however, is becoming increasingly harder to distinguish in today’s world. With today’s modern technology, leaders no longer have the ability to see the adversary’s army massing at the border in preparation for an attack.

It is also important to realize that preemptive strikes and preventive actions are not a type of war, but rather should be viewed as a “pathway to war.” In other words, a preemptive strike or a preventive action may signal the beginning of a war—but they are not in and of themselves distinct types of war. Any of the numerous types of war (e.g., limited war, total war, hegemonic war) can be started through the use of a preemptive strike or a preventive action.
action. Furthermore, since preemptive strikes or preventative actions involve the first use of force, they can only be taken before the outbreak of armed hostilities. Since these actions are designed to forestall an enemy attack, once such an attack has occurred, the opportunity to take preemptive or preventive action has passed.

While there are numerous arguments as to why leaders would adopt preemptive or preventative strategies, the historical record indicates that states rarely employ these types of policies. One of the possible reasons why the leadership of a state would be hesitant to launch a preemptive strike is that there are substantial political “strings” attached to these actions. The state risks being labeled the aggressor in the conflict and potentially alienating allies and friends in the process—thereby jeopardizing support that might be essential during the rest of the conflict and in later relations. Additionally, there is a great deal of uncertainty inherent in any war or armed conflict. A leader would want to be quite certain that an attack was truly imminent before he or she struck the blow that would start the war process. But, this level of certainty is rarely present, and leaders are, therefore, reluctant to utilize preemptive strikes. This does not mean that leaders never decide to launch preemptive strikes, but rather helps explain why their use is much rarer than might be otherwise expected.

Preference, Color

For most people, one of the first decisions of the day concerns color preference. College students learn that whether they are choosing an outfit for a job interview, designing a new product, or creating a Web site, the colors they choose greatly affect their final result. Psychologists report that color impression can account for 60 to 70 percent of consumer reaction. Therefore, understanding people’s color preferences becomes an important learning tool.

Color preferences change as a person develops and are in part determined by a person’s economic and social status. Education, environment, climate, and family heritage influence people’s favorite colors. Furthermore, people have color preferences for different objects like clothing, home decorations, and cars. A person may prefer a blue shirt, yellow walls, and a red car. Babies respond more readily to bright, primary colors than to pastel colors. The favorite color of most preschool children, up to the age of five, is bright red. Young children between five and ten years old prefer bright yellow.

As people grow and mature, their color preferences change. Adults may have learned to associate red with negative things, such as blood and fire, and so their color preference changes from childhood to adulthood. Adults have been found cross-culturally to favor blue over other colors. Adult women generally prefer blue-based colors, whereas men tend to prefer yellow-based tints. Even education levels and the degree of cultural sophistication seem to affect people’s color preferences. In general, highly educated and sophisticated people favor complex colors, those mixed with shades of black. In contrast, people with less education and lower income favor low-intensity, simple, or pure colors.

People respond differently to various colors depending also upon the climatic conditions in which they live. For example, Scandinavians have a preference for light yellows, bright whites, and sky blues, in contrast to their long, dark winter nights. San Franciscans, who live in an area that is often foggy and overcast, generally are not fond of gray. Conversely, cool gray is a popular color among people in Miami’s sunny, hot, and humid climate.

Ethnic heritage and traditions also affect color preferences. For instance, American couples most often prefer to dress brides in white, representing purity. Chinese typically wear white to funerals and prefer black or red colors for their wedding dresses, since these colors represent joy in their culture. Americans traditionally dress their newborns in blue or pink according to gender rather than personal individual preference.

Color preferences have changed over time. In the mid-1800s, bright colors were popular, but they were replaced by more subdued tertiary colors such as muddy reds, greens, browns, blues, pinks, and ambers in the 1870s. Pastel and cream colors came back into fashion in the 1890s, and were popular during the latter part of Queen Victoria’s (1819–1901) reign. But as fashions changed and furniture became more ornate, heavier, and more elaborate, room colors also became richer and darker.

Certain color preferences seem universal, such as that of “warm” and “cool” colors. People perceive red, orange,
and yellow to be warm colors, reflecting the natural association with the hot sun and flames. Blue and green shades are considered cool, in relation to cool water and shady leaves. Warm colors generally include magenta, red, orange, yellow, and yellow-green. Warm colors speed up our perception of time and produce feelings that are cozy and inviting. These colors are associated with excitement, happiness, and comfort. Cool colors generally include violet, blue, and green. Emotions associated with cool colors range from calm and peace to sadness, withdrawal, and repression.

COLOR PREFERENCE AND BUSINESS

Color-preference trends help sell products. Advertisers, fashion designers, and auto manufactures know that color influences the approval of or negative response to products or services. Commercials change fashion and cultural icons—Santa Claus, for example, used to wear a blue or green suit until Coca-Cola dressed him in their trademark colors red and white. Marketers use color preferences in products and advertising based on research and market tests. Along with personal preference, the typical meanings and effects of color are factors in product development and promotion. This happens because adults habitually relate colors to emotions.

Red elevates blood pressure, respiratory rate, and appetite. Red symbolizes heat, blood, passion, love, power, excitement, vitality, and aggression. In advertising, red grabs attention and stimulates people to make quick decisions. Pink, associated with sweetness, helps sell pastries and candies.

Orange causes people to feel energetic and is often found in the décor of fast food restaurants. Yellow represents the sun and is considered a spiritual color that symbolizes deity in many religions. Because yellow is the first color human eyes process, it attracts attention in advertising.

Indian mystics favor green because they believe it to be a combination of balance and harmony. Green, a sacred color to the Egyptians, represents the promise and rejuvenation of spring. In the Middle Ages, brides wore green to represent fertility. Green helps people relax, which makes it a popular color in hospitals.

Blue, the favorite color of adults, is disliked as a color around food. Most people prefer to dine surrounded by food-related colors, such as red strawberries, green apples, yellow bananas, and brown breads. Blue is the preferred color to wear to a job interview because people associate blue with loyalty and trustfulness.

Purple became related to perceptions of royalty and richness because the color was difficult to produce in ancient times. People think of luxury when they view purple. Leonardo da Vinci (1452–1519) favored purple lighting to enhance his creativity.

Brown is favored by men more than women. Connected to the earth and wood, brown is thought to represent solidity and strength.

Black, a color preferred by many for clothing, represents power, sophistication, and formality. Black also has contrary associations with witches and criminals. Black aids advertising materials by making other colors stand out in contrast and is the preferred type color for Web sites.

White represents cleanliness and purity to many people, who prefer white for automobiles, clothing, and interior design. White automobiles show up best at night. White clothing and interior spaces feel cooler in warm climates.

Color affects people, every day of their lives, on both the conscious and subconscious levels. With a thorough understanding of the effects of color preference, businesses can make wise decisions about product development and marketing. Individuals who understand their color preferences can make wise choices when selecting clothing, home furnishings, and automobiles.

PREFERENCE, GENDER

The term gender preference is confusing because it has a number of at best tangentially related meanings. For example, the term gender preference or sexual preference is used to describe the desire of biological parents for either a male or female child and—in the extreme—use a range of odious methods (e.g., infanticide and sex-selective abortions) to achieve that result. In patrilineal societies, the necessity for a male birth is straightforward. Less-developed societies tend to favor males for immediate utilitarian reasons and, eventually, as a primitive social security system. No such clear-cut historical and/or cultural rationales fully explain this phenomenon’s occurrence in developed countries, where adoptive parents...
strongly prefer to adopt girls. Another use of the term gender preference is to describe explicit or implicit job discrimination by which women are perceived as unable to perform certain skills (e.g., tasks requiring heavy lifting and other such manual labor). Overall though, the most ubiquitous use of the terms gender preference and sexual preference is in reference to sexual orientation.

Preference, meaning “to like better or best,” is a transitive verb: It requires a direct object. Given this use of the word, sexual orientation is considered synonymous with gender preference, for most discussion of sexual orientation is about whether an individual can be labeled as homosexual, heterosexual, or bisexual—that is, whether the “direct object” is the opposite gender, the same gender, or both. Most research and theories focus on homosexuality, not heterosexuality or bisexuality. Indeed, at the heart of most explorations of sexual orientation is an attempt to determine whether homosexuality is an outcome of nature or nurture. In an effort to attain the worthwhile goal of de-stigmatizing homosexuality and having it successfully removed from official lists of pathologies, activists have tended to fixate on biological determinism.

Acknowledging the difficulty of parsing out the influences of nature and nurture, Mustanski, Chivers, and Bailey proposed a “thought experiment” (2002, p. 94) that would involve an ideal test of whether hormones influence sexual orientation by a prenatal, organizational action. This experiment would require sex reassignment of a random sample of newborn males reared by adoptive parents blinded to the child’s natal sex. This unethical “experiment” exemplifies the extremes required to sort out these factors. Mustanski and colleagues summarized the findings of the last decade in the neurohormonal areas, including psychoneuroendocrinology, prenatal stress, cerebral asymmetry, neuroanatomy, anthropometrics, genetics, birth order, and developmental stability. They acknowledged some consistent findings, especially regarding genetics; however, their report concludes that it remains “puzzling … how and when these biological factors act and to what degree these factors influence sexual orientation” (p. 129). They also stated, “The term biological is frequently misunderstood and misused due to it being somewhat amorphous, given that all human behaviors are enacted by the brain and thus are in some sense biological” (p. 90). Thus, they speculated, “Rather than asking if sexual orientation is biological, we believe it is more fruitful to consider whether differences in sexual orientation primarily reflect differences in social experiences, differences in biologic factors unrelated to social experiences, or both. The ultimate goal of such research will be to understand the timing and mechanism of various etiological factors that influence sexual orientation” (p. 90).

In The Homosexual Matrix (1975), C. A. Trigg included a section titled “The Directional Controls of Sex.” Trigg stated that sexual choices made and actions taken are learned behaviors influenced by an individual experience in the context of a particular society. These learning processes are “rooted in a biological groundwork of slowly accumulating changes … over eons of mammalian evolution.” Trigg followed this path from sexual activity that is “rigorously regulated by specific physiologic controls” in lower mammals where “every movement is predetermined by key responses,” through primates whose “sexual patterns are neither stereotyped nor guided by specific signals; they are almost entirely dependent on individual learning,” culminating in humans with an enlarged cerebral cortex. Trigg described a “progressive relaxation of specific physiologic controls over sexuality” as the cerebral cortex assumes controls of voluntary behaviors such as sexuality. “Thus, human sexuality is exceedingly variable, deriving its directionality (especially its final targeting) from what is individually learned and experienced in personal and social settings” (pp. 12–15).

John Money created a list highlighting the endlessness of teasing out the antecedents for Trigg’s directionality and targeting. Describing what is required for what he labeled a lovenmap, Money contended that “the variables will be genomic status; hormonal history (prenatal and postnatal); sexual brain cell functioning; history of toxic, infectious, or traumatic exposure; infantile pairbonding; juvenile trophobonding; juvenile sexual rehearsal play; sex education; adolescent sexual history; amative history in imagery, ideation, and practice; and so on” (2003, p. 238).

Ultimately, in reference to what or who leads to sexual erotic arousal and attainment of orgasm, the terms sexual preference and gender preference are oxymorons because they imply that choice is at their core. Furthermore, such terms limit the “object” that stimulates the sexuerotic arousal and its sequela to gender-based categories. Such conceptualization marginalizes the entire phenomenon of paraphilias. Any review would be negligent if it focused on the power of the attraction of gender and ignored the same power that objects such as a shoe, a goat, or a child have on some individuals. Edward Albee’s realistic staging of “The Goat, or Who is Sylvia?” (2003) explores sexual orientation in a way that science has yet to attempt. Research into sexual preference needs to be broad enough to include such phenomena if it is to lead to an understanding of related conditions such as pedophilia. Use of gender preference as a synonym for sexual orientation limits such exploration.

PREFERENCES

Preferences are value judgments about the relative desirability of alternatives. In decision theory, the decision-maker's preferences are the criteria used to compare the alternatives available for choice. But preferences need not be related to choice: They may also represent how an entity values outcomes, or states of the world, that it does not choose. Depending on the setting, preferences may be objective or subjective.

In abstract, given a set $X$, a menu of alternatives that may be chosen or that may simply occur, an entity's preferences are a binary relation defined on $X$. Given two alternatives, $x$ and $y$, this relation answers the question “Is $x$ at least as good as $y$?” When, according to the entity, the answer is “yes,” one says that the entity weakly prefers $x$ to $y$ (denoted $x \succeq y$).

Historically, preferences were initially treated as cardinal objects: it was postulated that to any alternative $x$ one could attach a number $u(x)$, measuring the level of inner happiness, or utility, derived from it. Classical analyses in distributive justice and in economics during the eighteenth and nineteenth centuries, such as the utilitarianism of Jeremy Bentham (1748–1832) or the marginalism of William Stanley Jevons (1835–1882) and Carl Menger (1840–1921), required cardinal utilities. The independent contributions of Vilfredo Pareto (1848–1923) and Irving Fisher (1867–1947) in the late nineteenth century emphasized that only the ordinal information of preferences matters: That an entity prefers one alternative to another is merely a ranking. After the work of John Hicks (1904–1989) in the 1930s and Kenneth Arrow in the 1950s, it is commonly accepted that preferences are ordinal.

Suppose that a decision-maker (DM) is choosing from a menu $X$, and let $x$ and $y$ be two alternatives. It is clear that either DM likes $x$ at least as much as $y$, likes $y$ at least as much as $x$, is indifferent (both previous statements being true), or is unable to tell (neither statement is true). This means that $\succeq$ is a binary relation over $X$. If $x \succeq y$ while it is not true that $y \succeq x$, DM likes $x$ strictly better than $y$; this strict preference defines a second binary relation, $\succ$, the asymmetric part of $\succeq$. A third binary relation is given by the indifference of preferences, $\sim$, the symmetric part of $\succeq$.

DM has complete preferences if he or she is able to compare any pair of alternatives: either $x \succeq y$ or $y \succeq x$, for any $x$ and $y$. Preferences are said to be transitive if $x \succeq y$ and $y \succeq z$ imply $x \succeq z$. Complete and transitive preferences constitute a complete preorder, which is the most basic assumption on tastes of a decision-maker: DM is then said to be rational.

In more specific settings, additional structure allows for further properties. When $X$ is a field over the real numbers (for example, a Euclidean space), preferences are convex if any average of alternatives is preferred to the least-preferred averaged alternative. When a definition of more exists for $X$, preferences are said to be monotonic if more implies better. When $X$ is endowed with a topology, preferences are continuous if the at-least-as-good-as property is preserved under limits.

Preferences are representable if there exists a “utility” function, mapping $X$ into the real line, with the property that $x \succeq y$ if, and only if, the value of the mapping at $x$ is at least its value at $y$. In the 1950s Gerard Debreu (1921–2004) presented the seminal solution to the representability problem for continuous preferences. Representability does not mean that preferences have cardinal meaning: While any two functions representing given preferences contain, by construction, the same ordinal information, their cardinality may differ nontrivially. Given representable preferences, a property is ordinal if it is preserved upon increasing transformation of its representations, while cardinal properties are preserved only by affine, increasing transformations.

In economics, demand theory studies the individual choice of a bundle of commodities, at given prices and income, with preferences understood to be subjective and ordinal. In applications, a useful family of preferences delivers invariant substitution effects: The constant elasticity of substitution (CES) family includes linear preferences (perfect substitutability), Leontief preferences (perfect complementarity), and Cobb-Douglas preferences (unitary elasticity of substitution). Homothetic preferences deliver demand functions that are homogeneous of degree one in
income, while, with some qualification, quasi-linear preferences isolate all commodities but one from income effects.

When \( X \) represents an intertemporal situation, some structure is usually imposed on preferences. Suppose that \((x_0, x_1) \in X\) represents consumption in the present \((x_0)\) and in the future \((x_1)\). In this setting, it is usually assumed that the person is impatient to consume in the sense that \((x + \varepsilon, x - \varepsilon) > (x, x)\), for a small enough perturbation \(\varepsilon > 0\). In this case, a simplification is usually obtained by defining an instantaneous-utility (or felicity) function \(u\) on the real line, which represents the individual's satisfaction of consumption without intertemporal considerations, and a discount factor, \(\beta\), and by assuming that \(\succsim\) is represented by the function \(u(x_0, x_1) = u(x_0) + \beta u(x_1)\).

Here, the assumptions that \(\beta\) is increasing and \(\beta < 1\) model the hypotheses that the individual enjoys consumption and is impatient.

When the individual faces risk, the outcome of his or her choice is a random variable. In this case, \(X\) is a set of random variables (lotteries), \(\succsim\) ranks these variables ex-ante (in ignorance of the outcome that they will realize), and, in general, the standard analysis of preferences applies. As in the case of intertemporal preferences, a simplification is obtained via representation by utility functions. Leonard J. Savage (1917–1971) provided axioms that guarantee the existence of an expected utility representation, as defined by Daniel Bernoulli (1700–1782) in the eighteenth century: The ex-ante utility of a lottery is measured by the mathematical expectation of the well-being that the individual would derive from the outcome of the lottery were it not subject to risk, the induced random variable \(v(x)\). In this case, the felicity function has cardinal meaning: Only upon affine transformations is the representation of preferences preserved. Under expected utility, the curvature of function is used to measure individual dislike of risk. Arrow proposed two measures of risk aversion: absolute (the negative of the ratio of the second to the first derivatives of \(v\)) and relative (the absolute measure times the consumption level). An exponential representation of \(v\) exhibits constant absolute risk aversion, whereas an adaptation of the CES family yields constant relative risk aversion. Under uncertainty, completeness of preferences has been questioned: When unsure about the probabilities of different states of the world, individuals may be unable to compare all alternatives.

While research on choice often takes preferences as given, there are different theories about how humans form value judgments. In mathematical psychology, laboratory observation has led to the hypothesis that preferences (human and animal) are themselves random objects, which implies that choice itself is random (see, for example, the work of Duncan Luce and Patrick Suppes). Other prominent theories have considered the influence of experience and social interactions in the determination of preferences: While a basic view may take them as physiologically determined (so choice appears as a cognitive process), a broader view takes into account the influence of an individual's history or social context on the determination of tastes, from which choice appears as a behavioral phenomenon. These theories account for the learning processes that are embedded in sequential decision problems, for the effects of habit formation (for example, addictions) or for the influence of fashion or peer pressure on behavior (see the work of Gary Becker). Also, Amos Tversky (1937–1996) and Daniel Kahneman observed that the way in which a decision problem is framed seems to affect the choices of many individuals, which highlights the effects of perception on preferences. One more apparent anomaly of the standard theory arises in intertemporal problems, as evidence shows that often individuals choose not to delay the realization of a negative effect, which is at odds with the usual impatience postulate.

The problem of explaining how groups of individuals value alternatives has led to the definition of social preferences. An important difficulty in this direction was presented by Arrow in the mid-1950s: Under certain axioms, it is impossible to aggregate individual preferences into social preferences without the imposition of a "dictator" whose preferences are assumed for the whole society. Competing theories of social justice—for example, utilitarianism, Rawlsianism, or Robert Nozick's (1938–2002) libertarianism—provide prominent discussions of social preferences.

PREFERENCES, INTERDEPENDENT

Interdependent preferences models rely on the basic intuition that economic agents are not always purely self-interested. This intuition may sound unexceptional to noneconomists, but it is surprisingly so among the many economists who like parsimony and believe self-interest is a good approximation for most, or all, economic behavior.

Agent A has interdependent preferences whenever A’s utility function depends on those of other agents in the reference group. Consider two agents, A and B. A’s generic utility function with interdependent preferences is \( U = u(x) + \lambda x y, \) where \( u \) is the material utility component of the utility function and is a positive function of \( A \)’s material consumption \( x; v \) is the interdependent utility component of the utility function and can be a function of \( x, y, \lambda; \) and \( s \) is the interdependent component weight in the utility function, is bounded between \(-1 \) and \( 1, \) and can be a function of \( x, y, \) and \( \lambda. \) The utility function reduces to the self-interest case if \( s = 0. \)

The generic utility function encompasses most interdependent preferences models (nonadditive versions are also possible):

- Pure altruism where \( s > 0 \) and is a constant, and \( v \) is only a positive function of \( y. \) (Collard 1975).

- Pure envy where \( s < 0 \) and is a constant and \( v \) is a positive function of \( y \) and a nonpositive function of \( x. \) (Clark and Oswald 1998).

Distributional models that are a function of the distribution of incomes between the players (\( v \) is a function only of \( x \) and \( y, \) with the weight \( s \)) depending on how they relate to one another (Fehr and Schmidt 1999; Bolton and Ockenfels 2000).

- More complex psychological characterizations based on intentionality, as captured by the dependence on \( \lambda. \) (Levine 1998; Falk and Fischbacher 2001; Charness and Rabin 2002).

\( \lambda \) could also incorporate other psychological considerations, such as group identity (Akerlof and Kranton 2000; Darity et al. 2006). There is strong empirical evidence for interdependent preferences (for reviews, see Camerer, 2003; Sobel 2005; Zizzo 2000), with distributional models outperforming pure altruism or envy (Zizzo 2003b, 2004) and intentions mattering (Falk et al. 2003).

Four limitations of interdependent preferences are their cardinality, heterogeneity, endogeneity, and context-sensitivity. Cardinality means that an individual’s generic utility function requires strong interpersonal comparability of utility. Heterogeneity reflects the intuition that different people have different preferences, and the holy grail of capturing the empirical distributions of preferences is still at its early stages (see Burlando and Guala 2005 for an example). Endogeneity reflects the fact that environmental factors shape one’s interdependent preferences, and this has policy implications (Zizzo 2003a). Most seriously, interdependent preferences are sensitive to the context of the decision problem, that is, the way that the decision problem is perceived, with a large number of factors coming in and possibly interacting with one another (e.g., deservingness, social distance, communication, and so on) in ways that are poorly understood (Harrison and Johnson 2004; Konow 2000; Zizzo 2000, 2004). Adding dummy variables to ever more complex utility functions is hardly a solution; understanding the cognitive mechanisms underlying how agents perceive decision problems would be, but regretfully it is not a step that most economists are willing to take.

BIBLIOGRAPHY

Prejudice initially had been considered simple animosity or negative affect toward out-groups. However, beginning with Gordon Allport’s *The Nature of Prejudice* (1954), social scientists began to analyze the psychological construct in a more nuanced, differentiated manner. As a result, prejudice is now viewed as more than simple animosity. Led by Allport’s influential work, social psychologists in the late 1990s and early 2000s posited various intergroup emotion models to predict the types of prejudice elicited by different types of out-groups. These theories borrowed from work across the social sciences, including political science, economics, and evolutionary psychology. The gist of the models was that when we encounter an out-group member, an initial threat appraisal is based on his or her perceived social category. For instance, Susan Fiske and colleagues’ Stereotype Content Model argues that the interaction of perceived warmth (good or ill intention) and competence (ability to enact the intention) predict four types of emotional prejudices evoked by the out-group member. These models therefore allow for ambivalent emotions (e.g., pity, envy) beyond a simple like-dislike (e.g., pride, contempt) dimension, and, as a result, have allowed the landscape of prejudice to become much more detailed and comprehensive.

**PREJUDICE AS A DUAL-PROCESS ATTITUDE**

Prejudice occupies a dual-process model of attitude processes. Attitudes comprise the evaluations of attitude-objects, and research in the 1990s unearthed the central insight that attitudes include both an explicit and implicit component. The explicit component is the easily self-reported attitude in conscious awareness. The implicit component is often hidden from our consciousness, but does inform unintentional responses to out-groups. Moreover, the implicit attitude results from learned associations picked up from social environments. Prejudice is therefore thought to have an implicit and explicit component.

A dispute followed the adoption of this dual-process framework, and the field of prejudice serves as a primary battleground. The conflict involves whether one’s implicit attitude is really an attitude, and if it is, is it the same as one’s explicit attitude? For instance, one may hold egalitarian beliefs about social groups and as a result, not report any prejudiced feelings toward a certain social group. However, one’s implicit attitude is informed by the society one inhabits, and a stronger association between a group and negativity may lie deep in one’s unconscious. Hence, even though one does not explicitly hold any prejudiced attitudes, one’s implicit beliefs may contradict this position.

Prejudice occurs in the tripartite attitude structure of social bias. As such, prejudice consists of the emotional reaction evoked by social group members, is informed by the cognitive component or stereotype held about the perceived social group, and predicts the discrimination or behavior exhibited toward the group members. Prejudice as a concept has interested social scientists since World War II (1939–1945). The Holocaust drove a number of Jewish psychologists from Europe to the United States, where they initiated relevant research on conformity, obedience, aggression, and prejudice.

**Daniel John Zizzo**
Nevertheless, prejudice continues to be conceived in lay terms as simple animosity—a conception that makes it a taboo topic. The advent of the civil rights movement of the 1960s changed the social norm against prejudice, and expressing overtly prejudiced attitudes slowly became unacceptable, particularly to members of minority racial and ethnic groups. This norm change did not eliminate these prejudices, however; to the contrary: Institutional imbalances alone point to continued bias. Instead, social scientists argued that prejudiced attitudes are now more often held implicitly, adding more fire to the dual-process debate.

MEASUREMENT
This antiprejudice social norm’s demands persist today, preventing social science researchers from measuring prejudice simply by self-report. As a result, researchers tend to use subtle, indirect measures. For instance, instruments such as David Sears’s and John McConahay’s Modern Racism Scale assesses prejudiced attitudes toward black Americans via indirect questions that ask participants to make judgments about concerns related to disadvantaged minorities. The scale also has a component that measures traditional, “old-fashioned” blatant prejudice, as well as the modern, subtle component described above. This scale correlates with antiminority voting, among other behaviors.

Conceiving of prejudice in a dual-process framework also has led to the creation of implicit measures of prejudice. These measures test the strength of association between the attitude-object and negative constructs. The most popular such measure, the Implicit Association Test (IAT) developed by Anthony Greenwald and Mahzarin Banaji, uses reaction times to detect differences between the strength of prejudiced and unprejudiced associations. The test asks participants to categorize a prompt (either a word or a picture of a face) in the middle of a computer screen to either the left or the right category. In some trials one side is positive valence, the other negative, and in others, one represents a social category (black people) and the other another (white people). After several trials, valence and social category are both represented on either side (white-positive on one, black-negative on the other side) and the speed of categorization is assessed. These congruent trials are subtracted from incongruent trials where the opposite pairings are represented. A resulting faster time categorizing white-positive and black-negative pairings indicates that the association between the opposite pairings is more difficult for participants to make and thus, people show an implicit association, for example, between black and bad, white and good. The score on the IAT predicts a number of related phenomena such as nonverbal behavior in an interracial interaction, discrimination against out-groups, location on a liberal-conservative continuum, support for antidiscrimination policies such as affirmative action, and even neural activity in brain regions associated with negative affect (disgust and fear in particular).

NEURAL COMPONENTS OF PREJUDICE
Developments in technology and in social neuroscience have illuminated the neural underpinnings of prejudice. Both white and black participants have viewed white and black faces while their neural activity was recorded using functional Magnetic Resonance Imaging (fMRI). Participants across a number of studies consistently show greater brain activity in structures associated with emotional vigilance (amygdala) and disgust (insula) when viewing unfamiliar black faces than when viewing unfamiliar white faces (although the effect is always smaller for the black participants). Further, the amount of participants’ brain activity correlated with their scores on the IAT. These fMRI studies support the idea that prejudice may result in part from social learning, both because an IAT score indicates knowledge of the negative stereotype about a social group, and because blacks also show the effect.

Social context can reduce this neural activity simply by changing the social goal of the participants. When forced to think of people as individuals, not just category members, the increased activation in the amygdala provoked by viewing black faces diminishes below significance. Converging evidence also comes from electroencephalography (EEG). This technique likewise measures brain activity, but by detecting small electrical signals produced by neural cells as they fire. These studies also demonstrate that once the social goals change, social processing changes within 200 milliseconds. Changed social goals carry over even to subsequent nonsocial tasks, as whites’ efforts to appear unprejudiced cost them executive control in purely cognitive tasks.

REDUCTION OF PREJUDICE
Other than changing social goals, a few strategies reduce or eliminate prejudice, with varying degrees of success. The most successful, and ironically the most heavily debated, is the intergroup contact hypothesis proposed by Allport. According to the hypothesis, because social learning of stereotypes influences prejudice, contact with out-group members will eliminate the category-based dependence on stereotypes for information; instead, information will result from the nuanced interaction itself. The contact hypothesis utilizes potential friendship to diminish the limited, categorical perception of the out-group member based on stereotypes and replace it with a more nuanced, individuated perception. However, contact works to reduce prejudice under only certain conditions—cooperation rather than competition, equal status
PREJUDICE AS AN INDIVIDUAL DIFFERENCE

Certain individual differences make one more likely to hold prejudiced attitudes than not. Political ideologies, particularly right-wing authoritarian (RWA) beliefs, predict explicit levels of prejudice. An authoritarian individual demonstrates conformity to convention, authority-sanctioned aggression against deviants, and submission to authorities. Additionally, dominance-oriented personalities also tend to be more likely to hold prejudiced beliefs because they endorse the inevitability of group hierarchy. In this view, societies minimize group conflict by promoting ideologies that endorse discrimination and the dominant social hierarchy. Essentially, social dominance orientation prefers hierarchy over equality and dominance over parity. As a result, scales that measure these two constructs have also been used as indicators of prejudice. Prejudice level therefore can be predicted by political ideologies.

PRESENT ORIENTATION

SEE Time Orientation.
Congress. The president is also granted the authority to appoint, with the approval of the Senate, members of the cabinet, federal judges, ambassadors, and most high-ranking administrative officials.

As the head of the Executive Branch, the president has the power to execute executive orders. These directives inform officials in the executive branch of the president’s desired policy implementation. Since the executive branch encompasses the vast majority of the federal bureaucracy, the president can use executive orders to cover a wide array of policy goals. Presidents have utilized executive orders to intern Japanese-Americans during World War II (Order 9066), prohibit employment discrimination based on race or gender (Order 11246), and to create new agencies, such as the Federal Emergency Management Agency (Order 12148). Given the strength of presidential authority, the president’s power to mold policy through executive orders is clearly wide-ranging.

No formal review process exists for executive orders. Congress can pass laws that overturn executive orders, but since the president is virtually certain to veto such an act, Congress must gather enough votes to override a presidential veto in order to invalidate an executive order. Congress may also refuse to fund the section of the executive branch impacted by an executive order, though this also makes a veto more likely. Therefore, Congress rarely interferes with executive orders.

Although theoretically subject to review by the federal courts, the judiciary has overturned only two of the more than 13,000 executive orders issued by the office of the president since the Lincoln administration. Both rejections were grounded in the contention that the particular orders created new laws rather than modifying existing laws.

The power of the president in the area of foreign affairs clearly places the president at the forefront of the diplomatic apparatus. The president is specifically given the authority to receive all ambassadors and ministers from other nations. The president is also given the authority to negotiate and sign treaties with foreign nations pending Senate approval and to appoint ambassadors and other personnel to represent the interests of the United States abroad.

While the president’s powers in the legislative arena are somewhat limited, those limitations are as much in the eye of the beholder as anything. The president has veto authority, which gives him the power to prevent legislation from Congress from becoming law. While Congress has the power to override presidential vetoes, the supermajority needed for a successful override gives the president a significant advantage. In addition to the power to veto legislation, the president can call Congress into special session as deemed necessary. While he is required to inform Congress about the state of the union “from time to time,” he can use that event to recommend legislation to Congress that he believes to be necessary and appropriate.

THE SCOPE OF PRESIDENTIAL POWERS

In many ways, the power of the office of the presidency is shaped not by the Constitution, but by the individual. The remarkable specificity invested in the discussion of Congressional powers in Article I stands in stark contrast to the vague comments regarding presidential power in Article II (Pious 1979). While the authors of the Constitution had some general ideas of what they wanted the office to include, the relative lack of clarity has allowed occupants of the office to mold it to their own needs and desires.

The lack of clear direction regarding presidential power from the Constitution has allowed for varying interpretations of the extent of presidential authority. Throughout the nineteenth century, the assumption was that the president was limited to the powers expressly granted under the Constitution. This limited view of presidential power is generally referred to as the Whig theory of presidential authority. Presidents that subscribed to the Whig theory saw themselves primarily as bureaucratic administrators and ambassadors. As President James Buchanan (1791–1868) noted, “My duty is to execute the laws … and not my individual opinions” (quoted in Brinkley 1962, p.142).

Eventually, the Whig theory was deemed to be too limited and fell out of fashion at the beginning of the twentieth century. The replacement was Theodore Roosevelt’s (1858–1919) much broader stewardship theory. Stewardship theory argues that presidential authority extends to all areas not specifically forbidden by the Constitution or statutory law. While the Whig theory saw the president as limited to the powers clearly expressed in the Constitution, stewardship theory looks for all possible outlets for presidential power and authority. Stewardship theory has remained the dominant approach to presidential authority since the presidency of Franklin Roosevelt (1882–1945).

The third theory of presidential power, the unitary executive theory, argues that all power to execute laws and manage the executive branch falls to the president. This theory, which has generated much controversy in the first decade of the twenty-first century, essentially argues that Congress passes laws but the executive branch can interpret the laws in terms of implementation. This has led to presidents issuing “signing statements” that indicate whether or not the president intends to enforce the law as Congress had it written. The unitary executive theory is seen by many critics as a violation of the separation of
powers and an effort by the executive to supersede Congressional authority.

PRESIDENTIAL-CONGRESSIONAL RELATIONSHIPS
The nature of the relationship between the president and Congress is determined by several factors. The most important factor is the relative partisan control of each branch. When the majority in Congress is of the same party as the president (called unified government), the president is often able to work with the leadership to achieve their common policy goals. When the president and at least one chamber are controlled by opposing parties (often called divided government), presidents are often forced to compromise with the opposition party in order to pass legislation. The common perception is that presidents and Congress accomplish more under unified government compared to divided government, but the evidence indicates that this is likely not the case (Peterson 1990).

In addition to majority-minority status, the second major factor in determining presidential relations with Congress is the president's approval rating in the public. The more beloved the president is, the more likely Congress is to follow the president's lead. Congressional leaders realize that a popular president can campaign for or against them in any given election, and the president's popularity does have an impact on Congressional races. Conversely, an unpopular president can often find it difficult to move even small agenda items forward even under a unified government (Neustadt 1991).

In the era of broadcast media, presidents have often found it effective to use the public to generate pressure on Congress to pass a particular piece of legislation. This strategy, known as going public, is often used when presidents feel they need to exert external pressure on Congress to generate momentum (Kernell 2007). While these efforts do not always work, they give the president an additional, if unofficial, method to encourage Congressional action.

PRESIDENTIAL-JUDICIAL RELATIONSHIPS
As a general rule, presidents and the judicial branch do not interact on a regular basis. The most common ground they cover is in the process of selecting new members of the judiciary. Presidents have the authority to nominate all judges in the federal judicial system subject to the confirmation of the Senate. Presidents generally use this power to nominate judges with political beliefs similar to their own. Research shows that it is common for well over 90 percent of a president's judicial appointments to come from the same party as the president, and this becomes more relevant if the nomination involves an appellate court or the U.S. Supreme Court.

SEE Warren Report.

PRESSURE GROUPS
Pressure groups are private organizations that attempt to influence the lawmaking process to benefit the members they represent. Though the term has been applied to corporations and nonprofit organizations engaging in advo-
cacy, it properly refers only to organizations that represent factions of the public before government. Pressure groups form when individuals sharing some want or desire that can be realized through public policy mobilize, usually with the aid of an experienced political entrepreneur or wealthy patron. But in a highly diverse society such as the United States, it is rare that policy advancing the interests of one group can be produced without harming those of others. As lawmakers must choose between winners and losers when they divide public resources and enact regulation, pressure groups compete with each other to convince lawmakers to promote and protect their interests by offering campaign contributions and the votes of their members in elections.

The term pressure group is rarely used by social scientists in the early twenty-first century because how scholars view advocacy groups and lobbying has changed. It is more specific than the term interest group because it only conceives of groups as proactively pushing lawmakers to enact policies they desire at the expense of the electorate. This view was part of a larger belief first articulated by American behavioral scientist Arthur Bentley (1870–1957) in 1908, and which came to fruition with the behavioral revolution of the 1950s, that U.S. politics was only about competition among social factions mobilized as pressure groups. Law was simply the outcome of competition favoring the stronger group. For several reasons, however, this view declined in the late 1960s. First a major study in 1963 by Raymond Bauer and his colleagues articulated a more benign view of interest groups gaining access to lawmakers by providing services the latter required, not by pressuring them with threats of electorate reprisals. Second, in 1956 American sociologist C. Wright Mills argued that competition among advocacy groups was largely irrelevant because lawmaking was always rigged in favor of a ruling elite. Finally, in 1965 Mancur Olson demonstrated that the whole premise of many groups representing the interests of the public was untenable because the reason groups formed had little to do with any desire to influence policy.

This change from seeing groups as proactively wielding pressure also dampened an important debate among political scientists as to their importance as vehicles of representation in a democratic society. Believing the electorate to be too poorly organized and motivated to hold elected officials accountable through elections, scholars divided into two camps regarding the legitimacy of pressure groups. One, exemplified by political scientist Robert Dahl (1956), argued that groups representing minority factions were a legitimate form of representation, while the other, as described in The Semi-Sovereign People (1942) by E. E. Schattschneider, believed they inhibited political parties from electing slates of candidates that voters could hold responsible for the performance of government. With a decline in the belief of the real power of groups to pressure lawmakers, this debate also faded. New evidence, however, has emerged regarding how truly large and diverse the modern community of interest groups is in U.S. politics, and there is new attention in the early twenty-first century on whether groups might really be competing to shape policy. If so, it may be time to revive this debate over the role of pressure groups in democratic politics and return the term to the political lexicon.

**PRESTIGE**

Prestige refers to a person’s standing or estimation in the eyes of others. Having prestige means to be honored and respected. To understand the concept of prestige, it is useful to contrast it with other similar concepts related to the broader category of power, which refers to an individual’s relative capacity to influence other people’s outcomes in general.

How can prestige be differentiated from dominance, for example? Certainly, those with the power to dominate others can enjoy a kind of prestige. But definitions of prestige emphasize that we acquire prestige though our achievements, expertise, and admirable characteristics and behavior. This gives the prestigious person power, but it is usually a power to influence others through the positive emotions and attitudes elicited from them. We admire, respect, and even feel awe toward prestigious people, and these feelings are a major source of their power to influ-
ence us. In contrast, we are more likely to fear someone who is dominant.

The power inherent in the prestigious person has an earned, unforced quality. If we follow the lead of people with prestige, there is a sense in which they well and truly merit their power. The honor and respect that they inspire draws us in willingly, sometimes enthusiastically. Words such as *charisma* and *hero* fit in extraordinary cases of prestige. Thus, while prestige breeds imitation and emulation, dominance creates distance and the begrudging of advantage. Prestige promotes the loving gaze; dominance, the furtive glance. Prestige produces the desire for an autograph; dominance creates resentment and unease.

Ethnographic studies show that there are also differences in how the prestigious and the dominant person behave. Despite the legitimate foundations of prestige, it does not appear to cause grandstanding and arrogance in the possessor. Rather, one sees confidence blended with self-deprecation and gratitude. Dominance, on the other hand, involves swagger, implied threat at the very least, and the accentuating of superiority. Also, because prestige is earned rather than forced, the orientation of prestigious people is toward an understanding of those around them, the ones who award them prestige. Dominant people are alert to threats that forebode the taking away of their superiority and power.

All the differences between prestige and dominance hardly imply that these distinct sources of power cannot travel together. An army recruit can fear his sergeant and also respect him for the hard-earned medals. The sergeant may have no intention of striking fear in the recruit but may do so nonetheless because the capacity for punishment is inherent in the position. But that aspect of influence that flows from those hard-earned medals is different from the power that flows from holding the position itself.

It is worth emphasizing that prestige is linked to emotions, both in the person enjoying prestige and the person witnessing it in others. In evolutionary terms, these are rank-related emotions. Ranking on various characteristics is associated with access to resources that in turn lead to greater survival and reproductive success. It feels good to rank highly because one can enjoy the prestige that can come with high ranking (e.g., pride) and, correspondingly, it feels bad (e.g., shame) to have low rank. Thus, few of us are immune to the appeal of status and prestige. Most people seek the satisfactions of having prestige. And, presumably, one reason that prestigious individuals can create positive emotions in us is that they inspire us to do better ourselves.

An example of a domain in which the concept of prestige has intriguing explanatory power and where one finds considerable research focus is in marketing. This seems largely the result of the imitative, emulative potential in observing someone imbued with prestige who is also linked to products through marketing. This strategy makes good evolutionary sense, as modeling and learning from people admired for their achievements and remarkable qualities are likely to be a highly efficient way of operating. Although a typical feature of things that lead to prestige is that they are real and earned, consumer products simply linked to prestigious individuals can serve as proxies for the achievement of these features. These indicators, of course, may or may not correlate with actual characteristics in the particular case. The “status symbol” of an expensive car also driven by the rich and famous can mean actual wealth or credit card debt. The acquiring of status indicators is seductive, as it enables the apparent though often illusory achieving of prestige through short cuts. The use of the allure of prestige to affect consumers’ behavior is time-honored and is the source of an often-repeated phrase, “conspicuous consumption,” coined over a century ago by social scientist Thorstein Veblen.

It is tempting to see prestige in human groups as homologous to dominance processes in nonhumans, in which rank seems very much determined by physical power, fighting ability, and the like. However, rank in human groups is more associated with the possession of skills, expertise, and socially valued attributes. Although dominance resulting from physical power is far from irrelevant, depending on the particular culture, the ability to hold the attention of others because of earned qualities and admired attributes—the kind of things that produce prestige—is more of what leads to high rank. When Henry Kissinger noted that power is the ultimate aphrodisiac, he was not referring to the benefits, for example, of being a professional wrestler such as Gorgeous George but rather of having things relating to prestige more broadly defined. Interestingly, even Gorgeous George was a role model for Muhammad Ali, who learned some of the secrets of showmanship from this flamboyant wrestler. But Ali did not see defeating others in the boxing ring as an end in itself. He claimed that his boxing success was means to a broader goal of positive change in the world. He wanted to be a hero and inspiration for others—which indeed he was.

**PREVENTION SCIENCE**

Prevention science is an area of scholarship and research in the medical and social sciences that aims to establish principles of prevention and to apply them using tested and effective prevention-intervention programs (Schinke et al. 2003). A major goal in prevention science is to identify health risks or protective factors, along with the conditions that exert beneficial or detrimental effects on health (Hawkins et al. 1992), including, for example, the factors and conditions that lead to alcohol, tobacco, or drug addiction. Thus, prevention science contributes to the design of interventions that can enhance health or reduce the risk of disease or disorders.

The concept of prevention focuses on changing naturally occurring disease-producing conditions by administering interventions early in the disease process to reduce, eliminate, or alter the events that produce diseases. Individuals or populations that experience prolonged exposure to a number of risk factors have a higher likelihood of developing a certain disease or disorder. Such individuals constitute a high-risk group. Strategically, interventions are implemented according to two basic approaches: (1) eliminating or reducing exposure to risk factors; and (2) increasing exposure to protective factors. The most effective prevention interventions will incorporate both strategies.

The science of prevention emphasizes rigor in the design, testing, and implementation of the most potent (or most effective) prevention interventions. The efficacy of an intervention refers to its potency in producing a beneficial outcome under ideal conditions. Efficacy is evaluated scientifically using randomized controlled trials. The interventions developed from such trials can be taken from laboratory to community to test the intervention’s real-world effect. Randomized controlled trials examine the effect of a new intervention program when administered to an intervention group (the group that receives the improved or enhanced intervention) relative to a control group (the group that receives the standard or unimproved intervention). Under this design, researchers look for the occurrence of a greater or more beneficial posttest outcome in the intervention group as compared to the control group.

**AREAS OF EMPHASIS**

Prevention science focuses on the application of the principles of prevention in several areas. These areas include: (1) programs to reduce aggressive behavior in children and adolescents; (2) substance-abuse prevention programs that include teaching life skills or changing social norms; (3) community-level interventions to change laws or social ordinances to enhance public health, such as ordinances that require the use of seat belts; (4) scientific studies to test the effectiveness of prevention interventions using rigorous standards of evidence (Flay et al. 2005); and (5) various studies that generate new knowledge that adds to established principles of prevention and guides the application of these principles.

**COMMUNITY PARTNERSHIPS**

An important aspect of prevention science involves establishing working partnerships between prevention scientists and community members. Partners may include community members who can be described as stakeholders, or persons who have something to gain or lose from the implementation of a proposed community-based program. For example, a program that aims to reduce automobile accidents resulting from alcohol intoxication among adolescent drivers may encompass such stakeholders as parents, liquor-store owners, high school teachers, and other concerned individuals or groups within the community. Community partnerships, when well developed, set the stage for community input in the development of new prevention interventions. Such partnerships also promote community “buy in,” or a sense of local ownership that allows a prevention program to thrive within a community.

**CONTEMPORARY ISSUES**

The field of prevention science faces a number of challenging issues. One important issue involves finding ways to design programs that work with greater potency, that is,
programs that can increase the size of the prevention effect and the magnitude of healthy change. For example, how much can a program reduce the rate of smoking among adolescents who initiate or experiment with cigarette smoking? The more potent a program, the greater the effect size. Even the most effective community-based prevention programs generally exhibit only a small effect size, that is, they produce a small degree of change on specific outcome measures, such as a drop in the smoking rate among adolescents. Accordingly, one challenge facing prevention science involves increasing a prevention program’s magnitude of effect.

Another issue involves the fidelity-adaptation controversy. Tested and effective prevention programs are generally organized into instructional manuals that provide program-delivery personnel with information and a set of activities for program sessions. Such prevention-intervention programs, when delivered exactly as prescribed within program manuals, are considered to be implemented with high fidelity. This approach contrasts with the challenge of program adaptation, which involves changing or otherwise adjusting certain aspects of a tested and effective program with specific and well-planned modifications that are necessary to make the program relevant and viable when delivered within a community (Castro et al. 2004).

Another challenge involves identifying ways in which prevention-intervention programs can be delivered broadly in several sites. A related issue involves sustainability, that is, identifying ways of keeping a prevention program in operation into the future by convincing a community group or coalition to adopt the program as their own and to maintain the program in operation. These prevention-science challenges serve as important areas for research and program development.

POLICY-ORIENTED ISSUES
Social policy involves the development of guidelines that govern the decision-making process used by lawmakers, administrators, civic leaders, and others as they work to solve social problems. Prevention science can inform policymakers with scientific information and evidence-based knowledge to help them make better decisions in the interest of promoting public health. Thus, prevention science can contribute to social policy by: (1) informing policymakers on theories of human behavior and on ways to prevent disease and promote health; and (2) offering tested and effective intervention techniques and programs that can improve health in specific ways.

On a larger community or regional scale, however, such principles cannot be fully implemented without the support of local policymakers. The development of legislation and local ordinances can endorse, institutionalize, and maintain local prevention intervention programs, including, for example, ordinances prohibiting smoking in restaurants or the mandatory use of seatbelts while driving. These are examples of the contributions of prevention science to policy-related actions; in turn, social policy can aid in the implementation of prevention-science programs within diverse sectors of the community.

FUTURE ISSUES
Future challenges facing prevention science involve finding ways to design prevention programs that are more accessible, and thus more likely to be adopted and used by greater numbers of consumers. Prevention programs must also be user-friendly and widely available at an affordable cost, and they must allow consumer feedback to constantly monitor and improve the programs and keep them relevant to changing community needs. Moreover, making prevention programs more potent, whereby they produce greater and more enduring changes on targeted outcomes, remains a major challenge for prevention science. The use of new technologies and new forms of responsiveness to diverse cultural and economic consumer groups will aid in making prevention science and its interventions more socially relevant and more effective.

Prevention science is the product of ongoing research that aims to discover stable and generalizable new knowledge and intervention approaches. In the United States, this ongoing scientific endeavor aims to increase the capacity of prevention science to effectively meet the complex public health needs of growing and increasingly diverse sectors of the American population.

Price Indices

In 1927 Irving Fisher provided a simple definition of price indices in his classic book on index numbers, The Making of Index Numbers: A Study of Their Varieties, Tests, and Reliability.

An index number of prices, then, shows the average percentage change of prices from one period to another. The percentage change in the price of a single commodity from one time to another is, of course, found by dividing its price at the second time by its price at the first time. The ratio between these two prices is called the price relative of that one particular commodity in relation to those two particular times. An index number of the prices of a number of commodities is an average of their price relatives (p. 3).

To begin a discussion on price indices, some notation is important: Let \( p^0 = (p^0_1, \ldots, p^0_n) \) be a vector of prices for \( n \) goods in period 0. Let \( p^1 = (p^1_1, \ldots, p^1_n) \) be a vector of prices for the same \( n \) goods in period 1. Thus, the price relative of any good \( i \) is \( p^1_i / p^0_i \). A simple way of measuring the average change in all \( n \) prices from period 0 to period 1 is to take an average of the price relatives across all of the goods. For example, the arithmetic mean of the price relatives is \( P_{01} = \frac{1}{n} \sum_{i=1}^{n} \frac{p^1_i}{p^0_i} \) and the geometric mean of them is \( P_{01} = \prod_{i=1}^{n} \left( \frac{p^1_i}{p^0_i} \right)^{1/n} \).

As noted by E. Antony Selvanathan and D. S. Prasada Rao in their book Index Numbers: A Stochastic Approach, these simple measures:

- tend to consider price changes for all commodities to be equally important. However, in practice, movements of prices in essential items are considered to be more important and it is expected that any meaningful price index should accord weights to different price relatives. This principle leads to a class of weighted averages, where the weights are usually based on the value shares of each commodity (1994, pp. 19–20).

SOME WELL-KNOWN PRICE INDICES

Let \( q^0 = (q^0_1, \ldots, q^0_n) \) and \( q^1 = (q^1_1, \ldots, q^1_n) \) represent quantity vectors for the \( n \) goods in periods 0 and 1 respectively. Total expenditure in the two periods is the sum (across all \( n \) goods) of the prices multiplied by the corresponding quantities: \( Y^0 = \sum_{i=1}^{n} p^0_i q^0_i \) and \( Y^1 = \sum_{i=1}^{n} p^1_i q^1_i \). Thus, the expenditure shares for each good \( i \) are given by \( w^0_i = p^0_i q^0_i / Y^0 \) and \( w^1_i = p^1_i q^1_i / Y^1 \) for periods 0 and 1 respectively.

A price index is a function of the price and quantity vectors in two periods, which measures the change in the prices of the \( n \) goods between them. As in the previous section, the notation, \( P_{01} \), is used to denote a price index between periods 0 and 1. A price index can be interpreted in the same way as an individual price relative. If it is greater than one, it means that prices are increasing from period 0 to 1. If it is less than one, prices are decreasing. The rate of increase or decrease of an individual price can be computed by either subtracting one from the price relative, giving the growth rate \( (p^1_i / p^0_i) - 1 \) or taking the natural logarithms of the price relative, giving \( \ln(p^1_i / p^0_i) \) or \( \ln(p^1_i) - \ln(p^0_i) \). Similarly, the rate of increase or decrease in the prices of all \( n \) goods can be measured as either \( (P_{01} - 1) \) or \( \ln(P_{01}) \).

Given a price index, \( P_{01} \), one can always define a quantity index, \( Q_{01} \), implicitly from the following equation: \( P_{01} Q_{01} = Y^1 / Y^0 \), which means that the product of the price and quantity indices equals the ratio of total expenditure in the two periods.

A number of well-known price indices can be obtained by taking the weighted arithmetic or geometric means of the price relatives, where the weights depend on the expenditure shares. The Laspeyres price index, \( P_{01}^L \), is
obtained by taking a weighted arithmetic mean of the price relatives, where the weights are the expenditure shares for period 0. As explained by Selvanathan and Rao, the Paasche price index, \( P_{01}^P \), can be obtained in a similar fashion using hypothetical expenditure shares derived from period 0 prices and period 1 quantities. Although mathematically equivalent, the Laspeyres and Paasche price indices are usually defined as follows: \( P_{01}^L = \frac{\sum p_1^i q_0^i}{\sum p_0^i q_0^i} \) and \( P_{01}^P = \frac{\sum p_1^i q_1^i}{\sum p_1^i q_0^i} \). Fisher’s ideal price index, \( P_{01}^F \), is the geometric mean of the Laspeyres and Paasche price indices:

\[
P_{01}^F = \sqrt{P_{01}^L \cdot P_{01}^P} = \sqrt{\frac{\sum p_1^i q_0^i \sum p_1^i q_1^i}{\sum p_1^i q_0^i \sum p_1^i q_0^i}}.
\]

The Törnqvist-Heil price index, \( P_{01}^{TH} \), is the weighted geometric mean of the price relatives with weights that are the average of the expenditure shares from the two periods: \( P_{01}^{TH} = \prod_{i=1}^{n} \left( \frac{p_1^i}{p_0^i} \right)^{\frac{1}{2}(w_0^i + w_1^i)} \). An attractive property of this index is that its natural log is a weighted sum of the natural logs of the \( n \) component price relatives:

\[
\ln(P_{01}^{TH}) = \sum_{i=1}^{n} \frac{1}{2}(w_0^i + w_1^i) \ln(p_1^i / p_0^i).
\]

### The True Cost of Living Index and Substitution Bias

In his 1992 article “Economic Theory and the BEA’s Alternative Quantity and Price Indexes” Jack E. Tripllet discusses the connection between a price index for a set of consumer goods and services and a cost of living index:

a consumption price index should measure the change in the cost of maintaining a fixed, or constant, standard of living. If the price index holds the standard of living constant, then any increase in per capita consumption expenditures that exceeds the increase in the price index can be interpreted as an increase in the standard of living,… Thus, from the standard-of-living orientation, the price index measures the changing cost of a constant standard of living, and the quantity index measures increases or decreases in the standard of living (p. 49).

The true cost of living index was originally proposed in a 1924 paper by A. A. Könüs (an English translation was published in 1939). The true cost of living index is defined as the expenditure function, \( e(p, u) \), which gives the minimum expenditure needed to obtain a particular standard of living, \( u \), when prices are \( p \). The utility function, \( U(q) \), in turn, gives the utility, or standard of living, associated with the quantity vector, \( q \).

Thus, the true cost of living index measures the change in the minimum expenditure needed to maintain the standard of living associated with a particular vector of quantities, \( q \), as prices change from \( p^0 \) to \( p^1 \). (See W. E. Diewert’s 1981 article, “The Economic Theory of Index Numbers: A Survey,” for an extensive discussion of these concepts.)

The true cost of living index can be evaluated using any quantity vector. It could, for example, be evaluated using the quantities \( q^0 \), from period 0. In the following discussion, it will be assumed that \( e(p^0, U(q^0)) = \sum p_0^i q_0^i \), which means that the quantities \( q^0 \) are optimal given prices \( p^0 \). It would cost \( \sum p_1^i q_1^i \) to purchase the same vector of quantities in period 1 and doing so would ensure that the standard of living is unchanged. If relative prices have changed, however, it may be possible to achieve the same standard of living at a lower cost by substituting away from goods whose relative prices have increased toward goods whose relative prices have decreased. This reasoning implies that \( e(p^1, U(q^0)) \leq \sum p_1^i q_1^i \).

It follows that the Laspeyres index provides an upper bound on the true cost of living index when the standard of living is based on the quantities from period 0, since

\[
P_{01}^L = \frac{\sum p_1^i q_0^i}{\sum p_0^i q_0^i} \geq \frac{e(p^1, U(q^0))}{e(p^0, U(q^0))}.
\]

The upward bias in the Laspeyres index, relative to the true cost of living index, is a type of substitution bias. The same reasoning also implies that the Paasche index provides a lower bound on the true cost of living index when the standard of living is based on the period 1 quantities, since

\[
\frac{e(p^1, U(q^1))}{e(p^0, U(q^0))} \leq \frac{\sum p_1^i q_1^i}{\sum p_0^i q_1^i} = P_{01}^P.
\]

In general the true cost of living index depends on the choice of the quantity vector, so it would not be correct to say that the true cost of living index is bounded above and below by the Laspeyres and Paasche price indices respectively, since those upper and lower bounds are based on different quantities. A stronger result can be obtained if preferences are homothetic. As explained by Angus Deaton and John Muellbauer in their 1980 book, *Economics and Consumer Behavior*, homotheticity means that for some normalization of the utility function, doubling quantities doubles utility. Under homotheticity, it can be shown that the true cost of living does not depend on \( q \) and is, consequently, bounded above and
below by the Laspeyres and Paasche price indices respectively (see Diewert 1981). Nevertheless, homotheticity is a very strong assumption, since it implies that expenditure shares of the goods are independent of the level of total expenditure, which is contradicted by most empirical evidence (see Deaton and Muellbauer 1980).

SUPERLATIVE INDEXES

In his 1976 article, “Exact and Superlative Index Numbers,” Diewert provides a strong rationale for preferring certain price and quantity indices, which he termed superlative indexes. The Tornqvist-Theil price index and Fisher’s ideal price index are both superlative. Without going into precise technical details, essentially a price index is superlative if it can provide a good approximation to the true cost of living index even though the functional form of the expenditure function is not known (see Diewert’s 1976 and 1981 articles for further discussion, including the role of homotheticity in the theory of superlative indices).

The Laspeyres and Paasche price indices are not superlative, because they just measure the change in the cost of purchasing a fixed bundle of goods and, therefore, ignore substitution. As explained by Triplet:

Diewert showed that the Fisher Ideal index and the Tornqvist index are theoretically better measures of the cost of living than the traditional fixed-weighted Paasche or Laspeyres indexes. The superlative indexes accommodate substitution in consumer spending while holding living standards constant, something the Paasche and Laspeyres indexes do not do. From the view of theory, the Fisher Ideal formula and the Tornqvist formula are equally good; therefore, one can choose between the two on pragmatic grounds (1992, p. 50).

In fact, there are many other superlative indices besides the two that have been discussed.

The influential 1996 Boskin Commission report, Toward a More Accurate Measure of the Cost of Living, concluded that the consumer price index (CPI) overstated inflation in the United States by 1.1 percent per year in 1995–1996. The report further concluded that 0.4 percent of that bias could be attributed to upper and lower level substitution. The remainder of the bias was mostly attributed to quality change and new products. Robert J. Gordon, in his 2000 paper, “The Boskin Commission Report and Its Aftermath,” states:

It is noteworthy that few if any criticisms addressed the Commission’s basic recommendations that the CPI should become a COL [cost of living] index and that substitution at both the upper and lower level should be addressed within the framework of superlative index numbers (2000, p. 24).

CHAIN-WEIGHTING

Suppose there is price and quantity data for many periods denoted by $p_t$ and $q_t$, where $t = 0, 1, ..., T$ (for example, suppose there is annual data for twenty years). One can then compute price indexes from each period to the suc-
Price Setting and Price Taking

A time series covering more than two periods can be produced using the concept of chain-weighting. A chain-weighted time series can be constructed as follows: The value of the series, \( I_t \), for any period \( t \) is the previous value of the series, \( I_{t-1} \), multiplied by the corresponding price index for the two periods, so that \( I_t = I_{t-1} P_{t-1, t} \) for all \( t \). Thus, the growth rate of a chain-weighted index between adjacent periods is \( (I_t - I_{t-1})/I_{t-1} = P_{t-1, t} - 1 \). Any price index formula can be chain-weighted, although a superlative formula is preferable as previously discussed.

The Bureau of Economic Analysis (BEA) produces chain-type price indices for Personal Consumption Expenditures (PCE) and for Gross Domestic Product (GDP) for the United States, which are based on Fisher’s ideal formula (see A Guide to the National Income and Product Accounts of the United States published by BEA in 2006). See Triplet’s 1992 article, as well as Allan H. Young’s “Alternative Measures of Change in Real Output and Prices, Quarterly Estimates for 1959–92” (1993) for related discussion including alternatives to chain-weighting.

EMPIRICAL ILLUSTRATION

In this section, the use of price indices to measure inflation is illustrated. Annualized quarterly percentage changes in the chain-type price indices for PCE and GDP for the United States were calculated using data from 1960Q1 to 2006Q3. These two inflation measures are graphed in Figure 1 (PCE is black and GDP is grey).

These measures indicate that inflation was relatively low and stable in the early 1960s, but was higher in the mid to late 1960s. In the 1970s inflation was higher and more volatile and, in particular, oil shocks in 1973 and 1974 and 1979 and 1980 were associated with high rates of inflation. Inflation declined in the early 1980s and has been relatively low and stable in the 1990s and beyond.

PRICE SETTING AND PRICE TAKING

The determination of prices in different markets is usually characterized by two opposing strategies: price taking and price setting.

PRICE-TAKING STRATEGY

In this theoretical situation, which characterizes the limiting case of “pure competition,” market price is determined by the confrontation of a supply curve and a demand curve. With the usual assumption that the supply curve is increasing and the demand price is decreasing, there exists generally one intersection point. Other assumptions are that this intersection point is unique and stable, stability being warranted by adjustment processes, tâtonnement, which will lead to convergence on the equilibrium position. Here, the equilibrium point is unambiguously associated with the position where supply equals demand at price \( p \).

The equilibrium price is determined at the intersection of the supply curve and the demand curve (see Figure 1 left); this price is “given” to the firm (see Figure 1 right), which appears as the price taker. The firm’s production level will be determined at the intersection of this given price and its own marginal cost curve: the firm’s profit is maximized at the intersection, since the marginal cost equals the marginal revenue. Producing more would be inefficient, since the marginal cost will exceed the price; producing less would mean that the marginal cost is less than the price, and profit may be increased by increasing...
the production level. The individual firm makes a profit, since the price is superior to the average cost, and the total profit is obtained by multiplying the unit profit by the quantity produced.

In the conventional narrative, under long adjustment, new firms will appear in this market. The presence of positive profits induces new firms to enter. Hence, adjustment will be characterized by an increase in supply and a decrease in the market price, which will eliminate profit-making firms. Eventually, the market price level will coincide with the minimum average cost curve of the firm.

This price system plays an essential role in the information and regulation of general activity for producers and consumers. Equilibrium prices are scarcity indicators. Utility maximization implies that the market price represents the marginal value of the last dollar spent by consumers on the considered commodity. But the market equilibrium price also will represent production conditions, since the supply curve is derived from aggregation of the individual firm's marginal cost curves.

**PRICE-SETTING STRATEGIES**

Producers are generally able to fix, or set, their output price by taking into account quantities demanded by consumers.

**Monopoly** A monopolistic firm provides the whole product for the relevant market. The firm's demand and the market's demand are the same; hence, product demand, for which the firm is the only supplier, is a decreasing function of price. A monopoly will then maximize profit when it sets its level of output such that marginal cost is equal to marginal revenue. Given the profit-maximizing level of output, the monopolist then uses the demand curve to find the highest price that consumers are willing and able to pay for the profit-maximizing level of output. Consequently, in this case, quantity and price are determined simultaneously.

With the assumption of linearity of average and marginal receipt, representation is simple, as indicated in Figure 2.

More complicated strategies can be taken into account. In some cases, a monopoly may try, for instance, to maximize its turnover, which will be realized when marginal revenue equals zero, determining quantity and...
price. In another case, a monopoly will try to get balanced accounts—that is, zero profit—which will be realized when average cost equals average revenue. Such strategies obviously lead to more production, and can appear when a monopolist tries to avoid the “entry” of competitors.

Lastly, a monopolist may engage in marginal cost pricing, a strategy frequently used by publicly owned enterprises that guarantees optimal use of economic resources. The relevant level of production corresponds to equality of marginal cost and marginal revenue. Such a strategy, which appears as “optimal,” may imply deficits; consequently, economists have come to “second-best” solutions. Discrimination between different types of consumers or markets also can occur. Elasticity of demand is to be taken into account in price-setting strategies.

**Monopsony** In the symmetrical situation of a monopsony, a large number of suppliers of a homogeneous product or service face a unique buyer. The monopsony average unit curve is represented by the supplier’s curve. The monopsony’s marginal cost increases with quantity, and is situated above the average cost curve. With the simplified assumption that the monopsony sells its product at a fixed price, maximization of profits will be realized when the firm buys a quantity of raw materials (or labor services), \( q_M \), such that the value of its marginal product is equal to its marginal cost.

The purchase price paid to sellers, \( p_P \), will correspond to this quantity on the supply curve of the product. The monopsony will set the selling price on the product market, \( p_S \), at the point of the monopsony’s average receipt corresponding to the quantity sold (in this simplified case, no transformation of the product is taken into account); the profit unit is the difference between the “purchase price,” \( p_P \), and the “selling price,” \( p_S \).

**Monopolistic Competition** Monopolistic competition is a market structure characterized by a mixture of perfect competition and monopoly. There are a multiplicity of sellers, but each firm produces a unique product, although it is a product that is similar to those of other firms within the industrial group. So-called fast-food franchises, for example, are usually considered monopolistically competitive firms. As such, McDonald’s Big Mac hamburger is considered different from, but substitutable for, Burger King’s Whopper or Wendy’s Single. Or, more broadly, these different burgers are also competitive substitutes for KFC’s original fried chicken or Long John Silver’s fish and chips. Each producer then faces a downward-sloping demand curve that is affected by the decisions of both its competitors and its consumers. An increase in the number of sellers or a decrease in attractiveness of its products means a reduction in demand for a monopolistically competitive firm. It will sell less at all available prices. An increase in its own price means a reduction in the quantity demanded.

Similar to a monopoly, in the short run, a monopolistically competitive firm will maximize profit at the level of production such that marginal cost equals marginal revenue and the output price is consistent with consumer demand. However, if economic profits exist, this is an unstable situation; new competitors will progressively appear, which will decrease the firm’s receipts. The firm’s demand curve will progressively shift to the left until it is tangent to the average cost curve, a situation where the price will be set with zero profit. Further decrease in demand will lead to a new shift of the demand curve to the left, and the firm will disappear, since there is no further production level that will allow profitability.
Duopoly and Oligopoly In a duopoly or oligopoly, price setting by one competitor generally leads to price wars with fatal outcomes. Of course, it is always possible that firm $A$ draws customers from firm $B$ by a price decrease. But since it is also possible for $B$ to do the same, the only outcome, if a price war breaks out, is perfect competition equilibrium with price being equal to marginal cost, leading to ruin for one of the competitors. So price setting is generally not the solution, except when agreements between firms lead to a situation close to a monopoly. Such situations are common, and have developed among such firms as Boeing and Airbus, Pepsi and Coca-Cola, and Ford, General Motors, and Toyota.

The only strategy left, if one excludes agreements, collusion, and various nonmarket arrangements, is a determination of quantity produced by one or more competitors, the same price being settled by all. Such a situation will be stable or unstable, according to the behavior of competitors (i.e., their aggressiveness).

It must be recognized that in many industries, firms sell very similar, nonidentical products. In such markets, it is equally easy to represent firms as price choosers or quantity choosers.

**PRICE VS. QUANTITY ADJUSTMENT**

The phrase *price vs. quantity adjustment* refers to the debate over the way in which the economy adjusts over the business cycle. Neoclassical economics claims that the price mechanism (prices, wages, and interest rates) is the most important adjustment mechanism in the economy, whereas Keynesians believe that the quantity of output and employment are the primary forces of adjustment during the business cycle, and that downward price and wage flexibility in fact tend to make things worse.

The neoclassical view claims that under conditions of perfect competition, the economy is self-correcting and therefore would not require government intervention. When labor supply exceeds labor demand, competitive pressures would compel job-seekers to accept lower wages, which would encourage firms to hire more workers, thus increasing aggregate output and employment. If the newly produced output is entirely purchased by the newly hired workers, then workers’ savings would be equal to zero and the labor market would converge to full employment. However, under a more likely scenario, workers would save a portion of their income, which creates a potential problem for the self-adjusting mechanism of the market. The dual nature of saving means that on the one hand, from the workers’ perspective, saving is income not spent and is therefore a benign if not a desirable decision. On the other hand, from the firms’ perspective, saving is the equivalent of production not purchased. This problem, however, is dealt with in the loanable funds market. For neoclassical theory, the increased amount of savings would create an excess supply of savings relative to the demand for investment, thus driving down the interest rate due to bank competition to lend out their excess reserves. Consequently, a lower interest rate would encourage firms to borrow and invest in plant and equipment, thus continuing to hire workers up to the point where savings equal investment at full employment. The simultaneous adjustment of the labor market and loanable funds market requires price flexibility. Any obstacles to the price mechanism, such as minimum-wage laws, union bargaining wage policies, or central bank interest-rate target policies, would interfere with the self-regulating feature of the market, and are therefore undesirable.

The Keynesian view, however, was developed in the midst of the Great Depression in response to the neoclassical laissez-faire approach that dominated academic and policy circles alike. According to John Maynard Keynes (1883–1946), unemployment was not due to wage and price rigidities but rather to a lack of effective demand. Keynes rejected the loanable funds theory, which assumes that saving creates investment through interest-rate adjustments. From a macroeconomic perspective, the neoclassical model assumed that when aggregate consumption falls, aggregate saving would increase and would finance an equal amount of investment, which would keep aggregate demand high (thanks to the price mechanism). Keynes, on the other hand, showed that when the economy is in a recession or depression, consumer expectations turn negative due to unemployment and job insecurity. This leads to an aggregate reduction in consumer spending, leading to fewer sales, lower business revenues,
and a downturn in business expectations about future profits. Firms will slow down production (in an attempt to reduce inventories), cancel investment spending, and eventually lay off more workers, thus leading to further deterioration in business activity.

Keynes explained that a reduction in consumer spending is likely to be accompanied by a fall in investment spending, hence an overall reduction in effective demand. It is understandable that during a recession, consumers will not go out on a shopping spree, nor will firms expand their productive capacity when they have difficulty liquidating their inventories. Therefore, the only solution to boost the economy during the recession is to increase the level of effective demand through government spending in order to compensate for low consumption and investment spending.

In Keynesian economics, the key adjustment mechanism is the level of effective demand, with aggregate investment being the engine of the economy. More investment (financed through credit rather than savings) leads to higher aggregate income, which in turn fuels more consumption and generates a residual amount of aggregate savings. The increase in consumption will, in turn, generate more revenues and stimulate positive expectations about future profits, thus helping increase the level of investment, output, and employment.

Robert W. Clower (1965) and his student Axel Leijonhufvud (1967) launched a significant attack on the neoclassical interpretation of Keynes known as the Neoclassical-Keynesian Synthesis, which dominated macroeconomics through the standard IS-LM model. Clower and Leijonhufvud started the so-called disequilibrium Keynesianism movement, which culminated in the creation of the famous Barro-Grossman model in 1971. The IS-LM interpretation of Keynes made the Keynesian model a special case of a neoclassical model with sticky (nonflexible) prices. Leijonhufvud, however, showed that one could understand Keynes's theoretical contribution only in the context of the rejection of the Walrasian auctioneer coordinating mechanism. Both Clower and Leijonhufvud believed that the disequilibrium situation (i.e., unemployment and effective demand failure) is the result of information and coordination deficiencies, rather than wage and price stickiness. Clower explained that when unemployed workers offer their services to firms, this does not constitute a signal of an effective demand for goods. Additionally, the change in time preference of individual economic agents—say, an increase in saving—will result in a fall in effective demand, leading to a decrease in both employment and output levels. This coordination failure results, therefore, in involuntary unemployment according to Clower and Leijonhufvud.

With the rise of the rational expectations theory, Robert Barro and Herschel Grossman abandoned the disequilibrium approach and reunited with the standard equilibrium models of New Classical economics in the late 1970s. A revival of the same (mis)interpretation of Keynes in terms of sticky prices has been echoed by New Keynesian economists since the early 1990s, claiming that in reality prices and wages are not as flexible as in the neoclassical model because of things like efficiency wages, long-term labor contracts, menu costs, credit rationing, capital market imperfection, adverse selection, and adverse incentives. New Keynesian economics is, therefore, in favor of the price adjustment approach. The Keynesian quantity adjustment approach, however, argues that downward wage and price flexibility could make things worse by adding to consumer income insecurity and business uncertainty about investment and operating costs. Therefore, downward wage rigidity and price inflexibility reduce uncertainty and provide a more stable environment for economic growth. This debate, however, continues to be one of the most important ones at the theoretical and policy level, with arguments over the usefulness of minimum-wage laws, labor unions, and discretionary fiscal policy.

PRICES

Prices are the rates at which goods and services are exchanged for other goods and services, or for money. In a monetized economy, the term price usually connotes the amount of money for which a good or service is purchased or sold. While in conventional usage, the term price is applied only to goods and services, in economic analysis, wages, interest rates, rents, and other money exchange rates for specialized services are also considered prices.

Prices have a critical coordinating role in a market economy. Ordinarily, an increase in a good’s price conveys the information that it has become scarcer relative to the demand for it, either because its supply has fallen or because the demand for it has risen. A higher price induces existing producers to supply more of the good, and it attracts new entrants into an industry, since it tends to be associated with a higher-than-normal profit margin. Conversely, a declining price leads to reduced supply. Economists see these reactions as being exactly what is required for social efficiency, since resources should be withdrawn from uses that are less valued and drawn into uses that people value more.

Economist and social theorist Friedrich Hayek (1899–1992) argued that prices convey information about “global” (or society-wide) conditions to “local” actors (such as business owners), thereby solving a core informational problem faced by a society when it attempts to decide how best to allocate scarce resources. Hayek argued that the compactness or one-dimensionality of prices and the fact that they arise spontaneously as by-products of self-interested buying and selling activities makes them a uniquely economical way to coordinate society’s resource allocation process. In the “socialist calculation debate” of the 1940s, Hayek argued that it is impossible to solve the problem of efficiently allocating resources among productive activities in an economy of specialized producers without market-generated prices. During the middle decades of the twentieth century, the apparent economic viability of the Soviet Union and like economies was sometimes viewed as contradicting that claim; yet reform-minded economists in the socialist world asserted the validity of Hayek’s argument when political conditions allowed the matter to be discussed and their views ultimately prevailed.

Economic analysis distinguishes between nominal and real prices. The real price of a good is its price relative to the prices of other goods, while its nominal price is its price denominated in a currency the value of which may be changing over time. For example, if all nominal prices, including wages, were to double over a certain span of time, the real price of any given good would remain unchanged. The terminology reflects the idea that money is merely a medium of exchange without an intrinsic value of its own, and that what matters economically is therefore relative prices, including the purchasing power of people’s money incomes.

In practice, changes in a country’s price level can have real consequences. Inflations rarely affect all prices in perfect proportion. For this reason, and because of their asymmetric effect on, for instance, debtors versus creditors, they have significant distributional consequences. In a world of many countries and currencies, differences in rates of change in price levels affect international trade and payments. Unpredictable price changes increase risk, discouraging some investing and trading activities. Rapid price change can give rise to real costs, such as those associated with having to recalculate and reprice items frequently, the pressure to spend money as soon as it is earned, and the need to print and to carry large quantities of money.

Classical economists such as Adam Smith (1723–1790) distinguished between natural prices and market prices. While the terminology suggests that the “natural price” may have an underlying ethical quality, modern historians of economic thought generally understand the term to have been a reference to what would today be called a “long-run equilibrium price,” that is, the price at which a normal or average rate of profit can be earned. This is the level toward which a good’s price will adjust in the long run, through expansion or contraction of output.
Prices

by current producers and through exit of old and entry of new producers into the market. The “market price” is simply the price at which a good is sold at any given point in time. Since changes in supply or demand are always occurring, market prices are the prices we actually observe, while natural or long-run equilibrium prices are idealized or theoretical indicators of long-run tendencies.

Neoclassical economic theory teaches that allowing prices to be governed by the forces of supply and demand is the best way to permit them to play their role of signaling scarcity and guiding the ongoing reallocation of resources to their most valued ends. When governments intervene by setting price floors or ceilings, by taxing the sale of some goods but not others, by imposing tariffs on imports, by subsidizing some producers, or by directly determining what prices can be charged, prices become “distorted” and can no longer be counted upon to steer resource allocation toward efficient uses. In an economy in which prices are significantly distorted or controlled in these ways, it remains possible in principle to calculate what prices “should” be, that is, what they would be if market forces were permitted to determine prices freely and exclusively. The true “scarcity-reflecting” prices thus calculated are referred to by economic theorists as shadow prices, and they play important roles both in theoretical analysis and in some practical policy exercises.

On closer inspection, however, unregulated prices are not always the ideal, even according to neoclassical economic theory. Monopolists can push prices above levels associated with normal profit rates and efficient supply. The market prices of goods whose production destroys unpriced resources, such as clean air and water, systematically understate their true cost to society. Government interventions, such as setting a maximum price for a monopolist, breaking up monopolies so that competition will bring down prices and increase supply, or taxing polluters to force them to internalize costs they might otherwise impose on society, can at least in principle improve upon unregulated outcomes, although knowing how a government will act in practice requires an understanding of a range of political and economic factors.

Scholars who compare economic systems of different types emphasize that prices play more than a scarcity-signaling role in an economy. Prices also determine the relative incomes of different groups of economic actors. For example, higher real wages may mean lower profits and hence a smaller income gap between wage versus profit earners. A higher ratio between the wages of more-educated or skilled and less-educated or skilled workers was associated with rising income inequality in industrialized economies during the last decades of the twentieth century. In the heyday of the Soviet Union and other planned economies, planners set the wages of urban workers and the prices paid to farmers for their produce at levels consistent with the proportions of consumption versus investment desired by the political authorities. In this way, they used control over wages and prices as a method of dictating high rates of capital formation. Prices also functioned as accounting aids in the centrally planned economies. Their existence allowed economic planners to monitor the fulfillment of plan targets through a system of indicators (money flows) parallel to but distinct from indicators of physical input and output.

Their impact on the distribution of wealth, for instance between sellers and buyers, also explains why prices attract ethical attention, as epitomized by medieval European discussions of the “just price.” Sellers of a resource in plentiful supply, for example unskilled labor, cannot command high prices (wages) for their service under competitive conditions, resulting in their poverty in comparison with those selling a scarce resource—perhaps access to fertile land. Companies in the oil industry earning large profits in the wake of short-run supply shortfalls attract ethical and political attention because a higher price for transportation and heating fuel means poorer consumers and wealthier company owners. Governments sometimes try to prevent such transfers by fixing a maximum price. If the supply of the commodity in question is fixed, the price ceiling will cause demand to outstrip the available supply, which will then be “rationed” by some nonprice mechanism—perhaps willingness or ability to wait in line, perhaps rules governing who can purchase on which day of the week, or perhaps government issue of coupons in limited number. In some circumstances, rationing a scarce but crucial commodity may be preferable to letting market forces operate, but in eliminating the short-run windfall that would otherwise accrue to suppliers, it can also slow the expansion of output that would reduce the commodity’s scarcity in the long run.

Many governments set minimum wages, tax high incomes at steeper rates than low ones, or engage in other price-altering interventions in order to protect disadvantaged groups or moderate income inequalities. But governments face pressures from constituencies other than the poor, which also leads to price interventions. For example, tariffs preserve the profits of domestic producers at the expense of domestic consumers, and often also at the expense of forces promoting long-run competitiveness. The effect of prices on the distribution of income helps to explain a variety of government price-altering policies.

SEE ALSO Aggregate Demand and Supply Price; Interest, Natural Rate of; Long Period Analysis; Long Run; Rent; Shadow Prices; Short Period; Short Run; Spot Market; Wages
One of the more comprehensive approaches to the issue of primacy and recency effects has been in the persuasion literature. After World War II (1939–1945), the psychologist Carl Hovland (1912–1961) and his colleagues at Yale began to conduct research in order to understand how one could change people's attitudes, and what contextual factors might influence the persuasive impact of a message. In their 1957 book The Order of Presentation in Persuasion, Hovland and his colleagues began to explore the issue of order effects. Many studies found primacy effects such that postmessage attitudes were more influenced by the first speaker or set of arguments. However, other studies found a recency effect, such that the perceivers were more influenced by the last information they encountered. Additional studies demonstrated neither primacy nor recency effects.

In 1959 members of the Yale group hypothesized that persuasion effects should work much like memory. If two messages were presented sequentially and without delay, the first message would be more persuasive because it would interfere with the processing of the second message (resulting in primacy effects). However, if the second message was presented after a sufficient delay (e.g., one week), the first message would have decayed and the second (or more recent) message would be stronger in memory, resulting in greater persuasion. Although some data supported this hypothesis, the findings were not straightforward. Interestingly, memory in and of itself was not a strong predictor of persuasion. Other research has explored how the familiarity of the issue or the types of information may influence the occurrence of primacy and recency effects.

More recent research has suggested that contextual factors, such as people's ability and motivation to process the persuasive communication, are important determinants in whether primacy or recency will occur. Duane Wegener and his colleagues have presented evidence that when people are motivated and able to process information, they will demonstrate primacy effects. However, when motivation or ability are low, recency effects will tend to occur.

Perhaps not surprisingly, given the extensive work linking persuasion and memory, a number of researchers have explored how primacy and recency effects are manifested in human and animal learning and memory. Much of the research in this area is consistent with the findings in the persuasion literature. For example, contextual factors (e.g., type or topic of information, personal responsibility for outcomes, an individual's motivation to think about the topic) have been found to moderate primacy and recency effects in human memory. Reviews of the primacy/recency literature have highlighted that both primacy and recency effects are possible depending on the context in which the information is learned.

There has also been substantial research on primacy effects in the field of impression formation (the study of how we make judgments about the people we meet). Consistent with persuasion and memory research, Phillip Tetlock and his colleagues have found that as one's moti-
vation to be a complete information processor increases (e.g., one has personal responsibility for the decision, the outcome is perceived to be important), there is a tendency for primacy and recency effects to diminish. As motivation decreases (personal responsibility is low, people are tired), biases can occur.

Thus, the question remains: Is it better to speak first or second if you want to convince your audience? Of course, as with most psychological questions, the right answer is “it depends.” Most importantly, it depends on the knowledge, ability, and motivations of the audience. The impact of this research has been felt in many domains, including communications, marketing, and political science, among others. Indeed, as long as there is the possibility of gaining an advantage in the area of communications, it will be useful to conduct research to explore how and when order effects will occur.

PRIMARIES

Presidential and congressional primaries are intraparty election contests whereby candidates compete for the privilege of being the party’s general election nominee. Direct primaries in non-southern states originated with the Progressive Era of the early twentieth century as a way to move intraparty candidate selection away from corrupt state and local political bosses and urban machines. In southern states it was seen as a way to ensure continued political domination by one party. Although first pioneered at the local level, primaries spread to state and national offices and dominated candidate selection in U.S. Senate and House races by the mid-twentieth century. At the presidential level, reforms made after the contentious 1968 Democratic National Convention placed delegate selection, and hence the selection of the party nominee, in the hands of the party rank and file and away from party elites. This led to the proliferation and dominance of primaries in the presidential selection process. Primaries are generally considered a uniquely American institution.

TYPES AND TIMING

Participation and contest rules vary by state, party, and time. There are four general types of primaries: open, semi-open, closed, and runoff. In open primaries, voters choose the party’s primary in which they want to participate. Registered party members and independents who choose to participate can vote in a semi-open primary, though independents often have to change their party registration to that of party in whose primary they are participating. Only registered party members can vote in a closed primary. Primary runoffs, used especially in southern states, happen when no candidate receives a majority (more than 50%) of the vote. In a second primary or runoff, the top two vote getters face off. Runoffs may threaten a nominee’s general election chances if the opposing party’s candidate does not compete in a runoff. This potential disadvantage stems from the fact that one candidate has to expend resources on a second intraparty contest, while the other candidate can immediately shift focus to the interparty general election race.

A unique feature of the presidential nominating system is its extended and sequential nature. Primaries begin in New Hampshire, typically in late January or early February, and end with a slate of late states in mid-June. This serial process has given political elites and potential candidates the opportunity to move state primary dates up in the process, a procedure known as front-loading, to advantage their own political ambition or their state both politically and economically. Politically, early states have greater influence over who wins the nomination by sending signals to later voters about the viability and electability of the contenders and by helping to winnow candidates. Early states benefit economically due to increases in candidate spending, visits, mobilization efforts (including television ads), and media attention. Unfortunately, as the race progresses and it becomes clearer who the party nominee will be, the process produces disincentives for individual voter participation and reduces overall levels of voter turnout.

Congressional primaries also vary in timing and in the use of party endorsements. Some states schedule congressional primaries in early March and others as late as September of an election year. When states schedule presidential and congressional primaries on the same date, voter turnout levels increase. Some state parties attempt to influence voter choices through party endorsements. Endorsements may require candidates to meet a support threshold at the party convention to be placed on the primary ballot or may reward the top party convention vote getter with the first line of the primary ballot or with a designation as the party’s candidate.

Presidential and congressional incumbents seldom encounter a viable challenge in their primary bids, and
therefore these races are rarely competitive. The advantage incumbents have in fund-raising, name recognition, and perquisites of office tend to discourage competition. Strong primary challenges to incumbents are more likely to emerge when the challengers’ chances of winning the nomination and general election campaigns are greater. Incumbent members of Congress who face strong primary challengers typically are those involved in a scandal, such as charges of unethical behavior, or those who stray from representing their constituents’ interests. Although a surprising number of incumbents are unlikely to suffer a primary defeat amid allegations of wrongdoing, their precarious position makes them much more susceptible to a general election defeat. At the presidential level, incumbents are often challenged when their presidential approval is low. Since 1972 and the post-reform era, no presidential incumbent candidate has been defeated during the nomination campaign. In contrast, the out party contest is always competitive in presidential primaries, though this is less the case in congressional races. In open contests where there is no incumbent running, both parties generally draw a long list of nomination contenders, and the contests are more competitive.

IMPACT ON VOTERS AND PARTIES
Primates are candidate-centered contests where candidates act strategically, directly appealing to voters. Because party identification is not a voting cue, candidate attributes figure strongly in voter decision-making. Candidate-centered contests lead to intraparty factionalization as candidates directly compete against one another for voter support. Primary factionalization, however, appears to play at best a modest role in general election outcomes. Though early research in congressional and presidential races found that the party with the more divisive primary (defined as primaries with more contentious contests and usually based on margin of victory measures) loses votes in the general election race, late-twentieth-century models demonstrate little effect once candidate quality is considered. In a presidential contest, the party appears to heal from internal divisions as the focus of the race turns to the interparty general election fight; similar factors may be at work in congressional elections. Presidential research indicates that primary supporters of losers often turn their efforts to support the party or the party nominee in the general election campaign. At the congressional level, party activists who supported a losing candidate in a divisive primary were less active on behalf of the party nominee in the short term but still expressed interest in long-term party involvement. Thus primary campaigns are a unique opportunity for new party entrants, regardless of who they supported, to become mobilized and be a resource for general election party activity and other future party activity.

PRIMATES
No simple set of diagnostic characteristics defines “primates.” Rather, members of the order Primates share, to varying degrees, several suites of features that reflect a generally arboreal lifestyle. These attributes include:

1. Pentadactyl, prehensile hands and/or feet with nails (rather than claws) on the digits, of which the thumb and/or big toe are opposable.
2. Pronounced sensory emphasis on vision, notably through development of binocular and stereoscopic vision, as well as expansion of the visual cortex.
3. A generalized postcranial anatomy tending toward orthrograde (upright) posture.
4. A trend toward enlargement of the cerebral cortex, especially in monkeys and apes.

Primate taxonomy is debated, but 200 to 350 species are recognized. The majority are distributed in tropical and subtropical regions (roughly between the Tropics of Cancer and Capricorn) and throughout sub-Saharan Africa, south and southeast Asia, and South and Central America, although a few forms, such as the Japanese macaque, inhabit decidedly temperate habitats. Primates are chiefly rain forest and tropical forest dwellers, although many other biomes are ecologically relevant for certain groups, including savanna, woodland scrub, evergreen temperate forest, desert, and high-altitude eflinwood meadow.
Six major groups of primates are usefully distinguished:

1. Lemuriformes: the small nocturnal and larger diurnal lemurs of Madagascar.
2. Lorisiformes: the nocturnal, small-bodied lorises and bushbabies of Africa, south Asia, and island southeast Asia.
3. Tarsiiformes: the small, nocturnal tarsiers of Sumatra, Borneo, Sulawesi, and the Philippines.
4. Playtrrhini: the small- to large-bodied monkeys of Central and South America.
5. Cercopithecoidea: the medium- to large-bodied monkeys of Africa and Asia.
6. Hominoidea: the large apes of Africa and Asia, as well as humans.

The Lemuriformes and Lorisiformes form a coherent suborder, the Strepsirhini, unified by various traits, notably retention of the “rhinarium” (the naked, “wet” mammalian nose), increased reliance on olfaction, and greater seasonality of sexual behavior (“estrus”). Many strepsirhines are nocturnal. The second suborder, the Haplorhini, comprises the primates of the remaining three taxa, which exhibit predominantly diurnal habits (with the exception of tarsiers and one monkey species), enhanced vision and visual communication, and comparatively more continuous (less seasonal) sexual activity and reproduction.

DIETARY HABITS
Diversity and omnivory generally typify primate feeding strategies, rather than marked dietary specialization such as the bovid emphasis on grass. The three principal primate foods are fruits, leaves, and insects, but their relative dietary proportions vary considerably across species. Frugivory is most widely distributed: Most primates eat some fruit, and species strongly committed to frugivory are found in virtually every family. Figs (Moraceae, *Ficus* species) are an often a crucial keystone fruit source for forest primates. Because of metabolic implications of body size, folivory is more common among larger primates (greater than or equal to 13.5 pounds), such as the Old World “leaf monkeys” (Colobinae), neotropical woolly spider monkeys, and mountain gorillas. Conversely, insects are generally consumed in higher proportions by small primates (less than or equal to 3.5 pounds), such as the nocturnal strepsirhines, tarsiers, and neotropical marmosets, tamarins, and squirrel monkeys. Thus, with increasing body size, primate diets typically grade from insectivory, to insectivory-frugivory, frugivory, frugivory-folivory, and finally to folivory.

Some less common foods are nevertheless important for certain primates or in specific seasons. For example, marmosets, tamarins, and some strepsirhines rely heavily on exudates (gum), particularly seasonally. Underground storage organs (e.g., rhizomes, tubers, corms) are paramount in baboon foraging. These parts are modified stems or leaves in which the plant stores starch, minerals, and water (the potato being a well-known example utilized by humans). Nectar (for some lemurs and neotropical monkeys), grass (for gelada baboons), and seeds (for saki monkeys) are other examples. Carnivory (predation) occurs at significant rates only among baboons (*Papio* species), neotropical capuchin monkeys (*Cebus* species), and most notably chimpanzees (*Pan troglodytes*), the latter of which prey heavily upon red colobus monkeys. In contrast to the more individualistic and “opportunistic” prey capture of *Papio* and *Cebus*, chimpanzee “hunting” is performed simultaneously by multiple adult males. Researchers debate, however, whether male chimpanzees act independently of one another or coordinate their actions cooperatively through an organized division of labor (different hunting “roles”) and the use of foresight and mental attribution.

The omnivorous, “generalist” feeding inclination of primates has not precluded some adaptive specializations in dentition, physiology, and behavior. One noteworthy example is the gastrointestinal tract of Colobine monkeys: In a manner directly analogous to ruminants, it contains a large, multichambered stomach with variable chemical environments facilitating fermentation by symbiotic, cellulolytic bacteria. Thus, these monkeys are able to metabolize and subsist on otherwise difficult-to-digest, mature foliage.

SOCIAL SYSTEMS AND BEHAVIOR
Perhaps the most striking features of primate biology are the diversity and complexity of social systems. Many nocturnal strepsirhines—as well as the orangutan—live in “dispersed” societies in which adult males and females inhabit individually separate home ranges wherein daily activities are independently pursued. These home ranges may partly overlap and, in some species, differ in size between the sexes. Thus, a single polygynous male may occupy and defend from other males (territoriality) a large home range encompassing several females’ individual ranges. The original characterization of this arrangement as a “solitary” or “asocial” existence was understandable but inaccurate. Not only do “solitary” individuals interact at meaningful rates through indirect olfactory and vocal modalities, they may even aggregate regularly, for example, during feeding in orangutans, or at sleeping sites in some nocturnal strepsirhines. Recent mitochondrial DNA evidence from nocturnal lemurs reveals that such sleeping
aggregations comprise related females, thereby suggesting a "hidden" matrilineal dimension of as yet unclear significance in these dispersed social systems.

In contrast, the diurnal lemurs and all monkeys are highly gregarious, living in permanent social groups. With few exceptions, primate societies are generally closed (interaction—particularly affiliatively—between individuals of separate groups is rare) and age-graded (immatures of multiple ages/generations are present). The size and composition of groups vary greatly, as do the nature and patterning of constituent social relationships. This variation is expressed not only between species but also often across populations of the same species.

As with mammals generally, female primates often remain in their natal area and social unit for most if not all of their lives, whereas males disperse to other groups around the age of sexual maturity. The resulting female-bonded societies are thus based on "core" affiliative networks of related females—matrines—to which males associate in variable numbers and time periods.

For example, in some species (leaf monkeys and guenons) only one adult male lives in a group of several (typically three to ten) adult females and their offspring. Group membership is likely to confer polygynous reproductive advantages to males, although in at least some species, females copulate with other males in the population, which either live alone or in all-male "bachelor" units.

A "multimale" variant of this social system generally emerges with relatively larger female group sizes (e.g., ten to fifty). In such cases, three to fifteen adult (nonnatal) males typically reside with the females and their offspring. This social structure predominates in many of the Old World monkeys—notably the baboons and macaques—in addition to neotropical forms such as capuchin and squirrel monkeys. Relationships among females are highly differentiated, most often manifested as relatively rigid, linear dominance hierarchies organized around kinship (matrilineal relatedness). Several field and laboratory studies suggest a substantive cognitive dimension to nonhuman primate understanding of both "status" and "matrilineal kinship." Females invest heavily in activities that maintain their status, such as grooming and coalitionary support. Males similarly maintain dominance relationships that are, however, much more dynamic and unrelated to kinship.

In 10 to 15 percent of species—most notably the gibbons (Hylobatidae) and species of small neotropical monkeys—the group comprises one adult of each sex accompanied by several immature individuals of various ages. This social system was originally designated "monogamy" or the "nuclear family," but the term "social monogamy" is now preferred, particularly in light of avian research. Individuals in over 90 percent of bird species live and breed in heterosexual pairs, but genetic data have revealed that in many species extra-pair paternity may be significantly high (e.g., 40 to 50%). Although not all extra-pair sexual behavior results in fertilization, it is clear that one can no longer assume that sexual or reproductive monogamy results invariably from the monogamous social arrangement of birds. Correspondingly, "extra-pair" copulations, pair-bond termination ("divorce"), and "non-nuclear" families do occur among socially monogamous primates, but the generality and significance of these phenomena remains less clear than is the case for birds.

A polyandrous mating system is found in some marmosets and tamarins that live in groups comprising one adult female, two adult males, and youngsters of various ages. Males, as well as young adult offspring of either sex, are primarily responsible for care of the breeding female's (fraternal) twin offspring. The reproduction of adult female "caretakers" may, in fact, be behaviorally or physiologically suppressed by the dominant female.

Great ape societies are characterized by comparatively attenuated female relationships. As noted, female orangutans pursue largely separate lives. Although gorillas live in unimale, multifemale groups, dispersal of females (as well as males) at sexual maturity constrains the formation of matrilineal relationships; female gorillas instead direct more social attention to the resident male. Individual female chimpanzees occupy separate home ranges, interact infrequently, and have weak dominance relationships. Females disperse at sexual maturity, whereas males remain in their natal community. Thus, the kinship element of chimpanzee society is patrilineal in nature, based on relationships among related males that collectively maintain a territory encompassing the individual home ranges of numerous "solitary" females. These males and females may join and leave temporary foraging parties that vary greatly in size and composition, dynamically undergoing "fusion" and "fission" with other foraging parties and individuals of the community over days, if not hours. Cooperation in competition is a hallmark of male social life. Hunting is one such context, as is vying for dominance and the sometimes violent territorial aggression directed against neighboring communities of related males. Although the patrilineal structure and "fusion-fission" system of social foraging also characterizes bonobos (as well as neotropical spider monkeys), bonobos are noteworthy for the much more amicable nature of their social relationships and apparent female dominance over males.

Negotiating complex relationships involving status, kinship, and affiliation over their relatively long lives is believed to have been an important impetus in the evolution of social cognition in monkeys and, especially, apes.
PRIMING

People are influenced by their immediate environment, which includes the objects, situations, and persons they encounter. Indeed, features of the environment can affect psychological experiences and behaviors so subtly that people fail to notice these influences. Priming refers to an unobtrusive and momentary environmental influence on an individual's psychological experiences and behaviors. The term priming has also been used to describe the experimental technique researchers use to study these effects in the laboratory.

How does priming work? The dominant explanation posits that environmental features temporarily activate (prime) mentally represented concepts, such as attitudes, behaviors, emotions, goals, memories, stereotypes, and traits. For example, suppose that you encounter a dog on the street. This encounter activates the concept "dog" and its associated traits, such as "furry" and "loyal." Once activated, primed concepts become more likely to influence immediate cognitions (e.g., thoughts, judgments), feelings, and behaviors. So, if immediately after encountering the dog you are asked to name a characteristic that is important in a friend, you may be temporarily more likely to say "loyalty."

Importantly, priming effects occur automatically. That is, concepts can be activated without awareness and go on to bias overt responses in ways that people do not intend and cannot control. Supraliminal priming describes cases in which people are aware of an environmental cue, but are not aware of its influence on them, such as in the dog example above. In subliminal priming, people are not even aware of an environmental cue, yet it still influences them. As an example, imagine moviegoers who are flashed a brand of drink for fractions of a second, below the radar of conscious perception, and unwittingly choose it over other beverages.

Priming effects are explained by presuming that concepts are mentally represented in an associative network. Only when associations between concepts are strong does activating one concept temporarily activate others. Because associations are strengthened through repeated and consistent pairing, environmental cues that are encountered frequently can be powerful primes. Take, for instance, relationship partners. Among students who strongly associate their mothers with the goal to work hard, subliminally priming the word mother will activate the goal to "work hard" and the students will persist longer and perform better on a subsequent academic test (Shah 2003). Sometimes these strong associations arise through learned sociocultural stereotypes. An individual's group membership and stereotypes related to that group can be primed and help or hinder performance, depending on the stereotype activated. For instance, if Asian American women are asked about their gender, their quantitative performance on a subsequent test will suffer, but if asked about their ethnicity, their quantitative performance will improve (Shih, Pittinsky, and Ambady 1999). Priming stereotypes can also influence members of non-stereotyped groups. Young adults exposed to words related to the elderly stereotype, including sentimental and wrinkle, will subsequently walk down a corridor more slowly (Barth, Chen, and Burrows 1996).

The idea that behavior is not always consciously and intentionally guided raises questions about personal accountability. Suppose that a child behaves aggressively after watching violent television. To what extent is the child's aggression due to an active, intentional, consious thought process versus a passive process that does not require conscious intention or motivation on the part of the child? The roles attributed to conscious choice versus environmental determinism in explaining aggressive behavior, and other primed behaviors, have tremendous legal and policy implications.

PRIMITIVE ACCUMULATION

At any given time, the accumulation of capital depends on some already existing capital to invest in the production process. Therefore, it appears that the capitalist mode of production as a historical formation presupposes some “original” or “primitive” accumulation. Adam Smith (1723–1790) called this “previous accumulation” and saw it necessary for the advancement of the division of labor and therefore of what he calls the “productive powers of labour.” He argues that “the accumulation of stock must, in the nature of things, be previous to the division of labour, so labour can be more and more subdivided in proportion only as stock is previously more and more accumulated” (Smith [1776] 1976). So, for example, in a market society, “a weaver cannot apply himself entirely to his peculiar business, unless there is beforehand stored up somewhere, either in his own possession or in that of some other person, a stock sufficient to maintain him, and to supply him with the materials and tools of his work, till he has not only completed but sold his web. This accumulation must, evidently, be previous to his applying his industry for so long a time to such a peculiar business” (Smith [1776] 1976).

Smith, however, grounds this claim on the ideological belief that division of labor and “stock” is somehow a feature of modern industrial societies, since “in that rude state of society in which there is no division of labour, in which exchanges are seldom made, and in which every man provides everything for himself, it is not necessary that any stock should be accumulated or stored up before-hand, in order to carry on the business of society” (Smith [1776] 1976). This claim is in fact untrue and based on a methodological individualism typical of classical and neo-classical political economy: even in hunting and gathering societies arrows and containers are produced and “stocked” before the production of food and, typically, along a division of labor within a community of producers. By means of this ideological counterposition between a “primitive” and a modern industrial society, Smith does not need to explain the historical emergence of the peculiar form of the “previous accumulation” and of social division of labor correspondent to capitalist societies. He does address the question of how a social formation in which market relations play a marginal role in the reproduction of people’s livelihoods (as in European societies up to the eighteenth century) can turn into one in which capital is accumulated in the hands of the few, while the vast majority turn into wage laborers. According to classical political economy, this previous “accumulation of stock” resulted from thirst and abstinence by a section of the population. Along this line Adam Smith, who believed capitalist market relations to be harmonious and beneficial to its participants, never confronted the historical process that originated these market relations.

Marx rendered Smith’s term “previous” as “ursprünglich,” which then was translated into English as “primitive” (Perleman 2000, p. 25). In Part 8 of Volume 1 of Capital (1867), Karl Marx (1818–1883) discusses “the so-called Primitive Accumulation.” Marx adds the pejorative so-called to emphasize the flesh-and-blood history that formed the precondition of capitalist production. In highlighting the historical process, Marx developed a different meaning of primitive accumulation in that he linked it to the notion of capital as “class relation” rather than as “stock.” Given that “the capital-relation presupposes a complete separation between the workers and the ownership of the conditions for the realization of their labour,” it follows that “the process … which creates the capital-relation can be nothing other than the process which divorces the worker from the ownership of the conditions of his own labour.” By turning “the social means of subsistence and production … into capital, and the immediate producers … into wage-labourers,” this process is therefore the basis of class formation. Thus, the “so-called primitive accumulation … is nothing else than the historical process of divorcing the producer from the means of production” (Marx [1867] 1976, pp. 874–875).

To illustrate this process, Marx refers to English land enclosures during the sixteenth and seventeenth centuries; at times he also refers to the international dimension of primitive accumulation, such as the effect of the slave trade on Bristol and Liverpool. Furthermore, this process presupposes people’s resistance and struggles either implicitly, as in the case of the “bloody legislation” (Marx
Primitve Accumulation

[1867] 1976, pp. 896–904), or explicitly, as in the case of the “barbarous laws against combinations of workers [that] collapsed in 1825 in the face of the threatening attitude of the proletariat” (p. 903).

There are perhaps two main interpretative frameworks of the concept of primitive accumulation within a century-long debate in Marxist literature. One framework sees primitive accumulation as a one-time/place phenomenon, the occurrence of which leads to the development of capitalism. The other framework instead emphasizes the continuous occurrence of primitive accumulation as an integral part of capitalism, whatever its stage of development. The first approach perhaps has its roots in Vladimir Ilyich Lenin’s (1870–1924) early study, The Development of Capitalism in Russia (1899). In a polemic against the Populists, who believed that the absence of a developed market would prevent capitalist development in Russia, Lenin argued that the disappearance of the peasants and their communities was precisely the prerequisite for the creation of the capitalist market. Lenin saw this process as inevitable and ultimately positive, although he often underlined its contradictions.

The second interpretative framework seems to emerge from Rosa Luxemburg’s (1870–1919) The Accumulation of Capital (1913). Her work points toward an interpretation of primitive accumulation as an integral part of capitalism and its development. Luxemburg regards Marx’s schemes of expanded reproduction as a representation only of the mathematical conditions for accumulation in cases in which there are no more than two classes. In reality, she contends, capitalist production must rely on third parties (peasants, small independent producers, etc.) to be commodity buyers. Thus the enforcement of exchange relations between capitalist and noncapitalist production becomes necessary to realize surplus value. However, this exchange relation clashes with the social relations of noncapitalist production. In order to overcome the resistance to capital that arises from this clash, capital must resort to military and political violence. Here Luxemburg introduces a crucial thesis that, independently of the validity of her reasoning and interpretation of Marx’s schemes of reproduction, seems to open the way to considering primitive accumulation as an inherent, continuous element of capitalism; as such it encompasses the world as a whole, and implies political and military force.

Elements of Lenin’s and Luxemburg’s interpretations can be found in subsequent approaches, although until the 1970s the influence of Lenin’s approach seemed to be greater. For example, in his classic Studies in the Development of Capitalism (1963), which generated much debate on the transition from feudalism to capitalism, economist Maurice Dobb (1900–1976) used the category of primitive accumulation to denote a well-defined age of accumulation of property rights, better known as the mercantile age, which predates capitalist production (p. 178). Also, in the context of the early Soviet debate on the transition to socialism, Evgenii Alexeyevich Preobrazhensky (1886–1937), in his book The New Economics (1926), argued for the need for a primitive socialist accumulation.

More recently, widespread opposition to global neoliberal policies of privatization and cuts in social spending linked to structural adjustment have refocused scholars’ attention on the category of primitive accumulation as a continuous and integral element of capitalism, although within different interpretative frameworks. More specifically, and in relation to political-economic issues, emphasis has been put on crises of overproduction and profitability creating a need for capital to engage in primitive accumulation. Thus, George Caffentzis, for example, refers to neoliberal policies following the profitability crises of the 1970s as “New Enclosures” (1995), while more recently David Harvey refers to “accumulation by dispossession” in The New Imperialism (2003), situated in the contemporary crises of overproduction.

The role of social conflict and class relations in defining the continuous character of primitive accumulation is also clearly spelled out in the literature. In the essay “Separating the Doing and the Deed” (2004), Massimo De Angelis argues that in different historical phases, profit-driven capital must devise strategies of enclosures, either by promoting ex-novo areas of commodification vis-à-vis resistance, or by preserving old areas of commodification vis-à-vis ex-novo social struggles claiming “new commons.” Also, and complementarily, the typology of “new enclosures” and “new commons” has been seen to include a wide range of resources, such as land, water, and knowledge, among others.

Finally, it has been argued that the current attempt by states and international institutions to control demographic rates depends on the expropriation or “enclosure” of the body, of the sexual and reproductive powers of women, for the purpose of accumulating labor power and thus promoting capital’s valorization requirements. In Caliban and the Witch (2004), Silvia Federici shows that the witch-hunt terror in the sixteenth and seventeenth centuries opened the way for state attempts to control demographic rates and the reproduction of labor power, and she draws parallels with contemporary phenomena. In The Invention of Capitalism (2000), Michael Perelman has pointed out that primitive accumulation is linked to the social and sexual division of labor at least since the classical proponents of laissez-faire ideology (e.g., Adam Smith, James Steuart [1712–1780], and Edward Gibbon Wakefield [1796–1862]) were disguising a strategy for state-implemented primitive accumulation to shape the social division of labor.
PRIMITIVISM

Definitions of the term *primitivism* have varied historically in their intellectual usage and inflection across the disciplines. In its broadest sense, primitivism is an interest in or study of societies and cultures that have an ostensibly less developed notion of technological, intellectual, or social progress. Primitive societies defined thus are those that have not progressed to a state of technological advancement and are therefore perceived as antecedent to the industrialized economies of the West. While more recent definitions of primitivism in literature, visual arts, and anthropology have emphasized the temporal relationship between primitive societies and modernity, discourses on "otherness" are discernible in the Plato's *Republic* and in Homer's description of the Cyclops in *The Odyssey*.

As an intellectual practice or school of thought, primitivism can be broken down into two main strands of inquiry—firstly, that of the empirical study of primitive societies. This approach typified nineteenth-century anthropology, in which empirical study was carried out to chronologically ascribe customs and social structures of "primitive" societies in an evolutionary relationship to Western notions of modernity. Secondly, there is the study of cultural primitivism, which can be traced to Enlightenment philosophical interests in the ideas of nature versus reason seen most notably in Jean-Jacques Rousseau's *Discours sur les sciences et les arts* (1749) [*Discourse on the Sciences and the Arts*] and his idea of the noble savage in *Discours sur l'origine et les fondements de l'inégalité parmi les hommes* (1755) and later in Denis Diderot's *Supplément au voyage au voyage de Bougainville* (1772). In French literature, René Chateaubriand's two novellas, *Atala, ou les amours des deux sauvages dans le désert* (1801) and *Rêné* (1802) continued to explore this post-Enlightenment fascination with non-European cultures.

In the visual arts, earlier aesthetic explorations of the primitive in the work of artists Emil Nolde (1867–1956) and Paul Gauguin (1848–1903) in the nineteenth century began to develop in conjunction with new directions in the social sciences in the early twentieth century. In Europe this development was seen most clearly in the break from the disinterested intellectual focus of Victorian anthropology into the newer paradigms of cultural relativism of ethnology and ethnography that had been emerging since Franz Boas wrote *The Mind of Primitive Man* in 1911 (1983) in which he set out a new model of cultural relativism for the anthropological study of non-Western societies. This approach was taken up and developed by later cultural anthropology in Bronislaw Malinowski's *Argonauts of the Western Pacific* (1922) and *The Sexual Life of Savages in North-Western Melanesia* (1929).

The formation in 1926 of the Institut d’Ethnologie in Paris by ethnologist Marcel Mauss (1872–1950), philosopher Lucien Lévy-Bruhl (1857–1939), and ethnologist Paul Rivet (1876–1958) heralded a new era of ethnographic enquiry into the concept of the primitive in the social sciences. Large-scale interdisciplinary ethnographic projects such as the Mission Dakar Djibouti 1931–1933 brought together writers, artists, sociologists, and anthropologists to work on new conceptualizations of cultural primitivism. In Europe this development of the

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION 465
term *primitivism* was simultaneous with the emergence of the modernist movement in art and literature and a new aesthetic engagement with a notion of the primitive that found diverse expressions in painting, as in Pablo Picasso’s *Les Demoiselles d’Avignon* (1907), inspired by his contact with African and Oceanic art in the Musée du Trocadéro. This was also found in the modernist avant-garde performances in the dadaist Cabaret Voltaire and in poetry in Blaise Cendrars’s “Prose of the Trans—Siberian” (1913) and Guillaume Apollinaire’s “Zone” (1913).

This renewed literary interest in primitivism was in part motivated by several texts that explored psychology, society, and religion from new intellectual and cultural perspectives: Sir James George Frazer’s *The Golden Bough: A Study in Magic and Religion*, first published in 1890 (1900), the work of Sigmund Freud in *Totem and Taboo: Some Points of Agreement between the Psychic Lives of Savages and Neurotics* (2000 [1913]) and later in *Civilization and Its Discontents* (2005 [1930]). All in some way influenced some of the major works of European literary modernism such as Joseph Conrad’s *Heart of Darkness* (1899), Thomas Mann’s *Death in Venice* (1912), and D. H. Lawrence’s *The Plumed Serpent* (1926).

Frazer’s study of the primitive roots of religion was the first of its kind to examine religious practices and rituals from a cultural rather than a theological perspective, and this marked a twentieth-century movement away from simple evolutionary binary divisions between notions of “primitive” and “civilized” forms of religious practices to more culturally relativist approaches influenced by the theories of Karl Marx (1818–1883), Émile Durkheim (1858–1917), and Max Weber (1864–1920).

**PRINCIPAL COMPONENT ANALYSIS**

**SEE** Factor Analysis.

**PRINCIPAL COMPONENTS**

Quantitative social science often involves measurements of several variables on a number of individuals. Principal components are *variates*, linear combinations of variables that have special properties in terms of variances. Variates hav-
ing large variance across the population are of special interest, in that they best distinguish among individuals in it.

It is often possible to understand or interpret a set of variables through a few variates. Also, sometimes relationships are not exhibited in the observed variables but rather in combinations of them; principal components can reveal such relationships.

Variates are expressions such as $6X + 8Y$ or $2X + 3Y + 4Z$. The sum and difference are special cases. For example, instead of a verbal $IQ$, $V$, and a quantitative $IQ$, $Q$, one might study their sum $V + Q$ and their difference $V - Q$. If it is known that the sum is 260 and the difference is 20, one can see that $V$ is 140 and $Q$ is 120. If the original variables are replaced by the same number of variates, all the information in the original variables is retained; the original values could be recovered.

It is useful to transform to uncorrelated variates, containing separate information. This can be done in many ways, so the transformation can be chosen to have further desirable properties. In principal components analysis, first the variate having the largest possible variance is found. In doing this, the sizes of the coefficients (multipliers of the variables) must be controlled. For example, the variance of $6X + 8Y$ is 100 times that of $0.6X + 0.8Y$. Only normalized variates, like the latter, whose coefficients have a sum of squares of one, are considered in defining principal components.

The first principal component is the normalized variate having maximum variance. The second principal component is the normalized variate having maximal variance among those uncorrelated with the first. The third principal component is that having maximal variance among those uncorrelated with the first two, and so on. In short, then, the principal components are uncorrelated linear combinations of maximal variance.

Principal components are computed from variances and covariances that depend upon the units of measurement, so often the data are first converted to z-scores, each value being replaced by the number of standard deviations above or below the mean for that variable. The resulting variables have variances equal to 1. Sometimes the original data are used, especially when the variables have the same units of measurement, for example when they are measurements of several dimensions of the same object. The operations obtaining principal components are performed on the covariance matrix. Use of $z$ scores is equivalent to using the correlation matrix rather than the covariance matrix.

Principal component analysis approximates the variables using a small number of variates. In exploratory studies involving many variables, some may be dropped later if they have small coefficients in the first several principal components. To obtain a two-dimensional scatterplot of a multivariate sample, the first and second principal components are used.

Principal components can be inputs to another procedure, such as multiple regression or cluster analysis. Factor analysis describes each variable as having a part that is explained by factors shared with other variables and a unique part that is not so explained; it analyzes the shared variance of the set of variables. Once a reduction to a smaller number of factors or principal components is made, often the pattern of coefficients leads to an interpretation of them. Here caution must be exercised. Since there are many mathematically equivalent solutions, such an interpretation is not unique; it is an interpretation, not the interpretation.

Harold Hotelling (1895–1973), an American economist and statistician, developed many of the ideas of principal components.

PRINCIPAL-AGENT MODELS

Black’s Law Dictionary (1999) defines a principal as someone “who authorizes another to act on his or her behalf as an agent.” The principal-agent relationship appears in many contexts. An employee acts on behalf of an employer in the sense that the employer receives certain benefits from the employee’s actions. Less obviously, there is a principal-agent relationship between an insurance company and an insuree, in the sense that the insuree’s actions subsequent to the insurance affect the principal, in effect, via payouts.

In economics, principal-agent problems generally refer to the analysis of contracts between individuals in which the individuals have conflicting goals and where asymmetric information is present. The labor contract is a classic example. A firm, when hiring a worker, wants maximum effort from the worker, whereas in many cases the worker prefers not to perform at the maximum level. If the contract between the two provides a fixed wage independent of the effort of the worker, then the worker has no incentive to work hard. The obvious solution is to
make the wage depend on the worker’s effort. However, it is often the case that the relevant behavior is unobservable. While one can in principle identify the effort of an isolated worker who is producing objects, one cannot do this in more complicated environments, such as those in which many factors interact to determine output. This example illustrates some of the basic issues that exist in designing contracts in modern economies; namely, the dependence of the payoffs of the participants in a contract on the behaviors of others when these behaviors cannot be observed and can only be enforced by the terms of the contract.

This example of a principal-agent problem has focused on questions of hidden actions; that is, one agent takes an action that is unobservable to another, which affects the benefits to the contract between them. Other principal-agent models focus on the question of hidden information, in which one agent must reveal information to another in order to determine actions under the contract. The classic example of this problem concerns the writing of a contract when the disutility of a job is unknown. If the compensation a worker receives is increasing in the disutility he or she experiences, then he or she will have an incentive to claim the job is unpleasant regardless of the truth.

The analysis of principal-agent problems has led to a large number of substantive insights. For example, insurance deductibles can be understood as a way to create incentives for insureds to avoid overuse of medical care for which they are covered. These models have also been used to understand how landowners structure sharecropper contracts to elicit effort from tenants. The general problem is to structure the contract to obtain maximum expected utility for the principal subject to a constraint that the agent receives some prespecified level of utility. In their 1983 article Sanford Grossman and Oliver Hart discussed the design of optimal incentive schemes in this setting. Roy Radner demonstrated how the principal can improve design of optimal contracts by exploiting information gleaned in a repeated game setting. William Brock and Lewis Evans showed how continuous record asymptotics can be used to uncover hidden actions by agents.

Joseph Stiglitz pioneered a number of the ideas in the principal-agent literature. His Nobel Prize lecture “Information and the Change in Paradigm in Economics” (2002) is an enlightening summary of his thought. Other leading writers in this area include Grossman, Hart, Bengt Holmstrom, Paul Milgrom, James Mirrlees, Roger Myerson, Radner, and Stephen Ross; Ross’s 1973 article is an early explicit use of the terms principals and agents in modern economic theory. The contemporary theory of principal-agent models is well surveyed in Andreu Mas-Colell, Michael Whinston, and Jerry Green’s book *Microeconomic Theory* (1995).

PRIORS

PRISON INDUSTRY

Fueled by “get tough on crime” policies, incarceration rates in several developed countries have increased considerably in recent years. For instance, Australia’s incarceration rate increased from 89 per 100,000 persons in 1992 to 163 per 100,000 in 2004, while Great Britain’s incarceration rate grew from 90 per 100,000 in 1992 to 141 per 100,000 in 2004, according to the International Centre for Prison Studies at King’s College London. The increase in incarceration rates has been most prominent in the United States; as of mid-year 2005, there were 2,186,230 inmates behind bars, with two-thirds in federal or state prisons and one-third in local jails, as cited by the U.S. Bureau of Justice Statistics (2006). Approximately 60 percent of those incarcerated in local jails have not been convicted of any crime. The United States incarceration rate in 2005 was 730 per
100,000, a rate that is higher than even the Russian Federation (at 581 per 100,000). In fact, the United States imprisons approximately 500,000 more individuals than China, which has a population five times greater than the United States. Furthermore, while the United States has 5 percent of the world’s population, it holds 25 percent of the world’s prison population. The United States diverts substantial economic resources to the criminal justice system. In 2003, the country spent $185 billion for police protection, corrections, and judicial activities, representing a 418 percent increase since 1982 (U.S. Department of Justice 2006). In the same year, the justice system employed nearly 2.4 million individuals.

While some believe that the recent increases in incarceration rates are related to increases in crime, most scientific studies of this issue find no such relationship. Instead, fear of crime and the demonization of criminals by the media and politicians have led to support for policies that result in more people being incarcerated, and for longer periods of time. These policies include mandatory minimum sentencing, “three strikes and you’re out” laws, truth-in-sentencing legislation (which requires inmates to serve 85 percent of their sentences), and the war on drugs.

Among the major drivers and beneficiaries of these policies and the resultant incarceration binge are constituents of the prison-industrial complex. These growing incarceration rates have created a powerful coalition of vested-interest groups with stakes in keeping prisons full and building more of them. These interests include private prison companies and individuals who lobby for them; financial institutions that underwrite loans and bond issues to finance prison construction; companies involved in the construction, operation, and maintenance of correctional facilities; corporations that use prisoners as a cheap source of labor; state and local politicians with prisons in their districts, or who covet such facilities due to the presumed economic development they will stimulate; individuals employed in the criminal justice system, in particular those who serve as correctional officers in prisons; and companies that provide products and services such as food, medical, transportation, furniture, and telephone services to prisons. Under the laws of several states, prisoners can make only collect phone calls, and this situation results in considerable profit for both states and major telephone companies, with the latter charging up to six times the regular rates plus an automatic “connect fee” of $1.50 to $3.00 per inmate call. AT&T estimates that nationally, inmates place $1 billion per year in long-distance calls, and profits from contracts with MCI and GTE netted the state of California more than $16 million in 1998, while the state of New York received $21.2 million from phone-call commissions in 1997, according to Joseph T. Hallinan in his study *Going up the River: Travels in a Prison Nation* (2001). There is also a burgeoning specialty industry that sells fencing, handcuffs, drug detectors, protective vests, and other security devices to prisons.

Given the considerable profits enjoyed by corporations enriched by the booming prison industry, several communities have competed to host prisons on the assumption that prisons will generate local economic activity in the form of jobs and tax revenues. Recent research, however, casts doubt on this assumption. Prison towns often end up with a net decline in employment, notes Gregory Hooks et al. in *Social Science Quarterly* (2004). This suggests that the benefits are being reaped by distant corporations, not the local communities. This is largely because prisons hire relatively few local employees and because unpaid inmate work crews often compete with local residents for low-wage jobs.

Similar to the military-industrial complex, the prison-industrial complex has an internal logic that allows it to benefit and expand regardless of whether it is a success or failure. If the United States loses a war, it requires more spending to ensure that it keeps on winning. In a similar fashion, if crime is increasing, we need more prisons to lower crime rates; if crime is decreasing, we need more prisons to ensure it continues to decrease (Donziger 1996).

PRISON PSYCHOLOGY

Prison psychology encompasses both clinical mental health practice within correctional settings and the study of psychological aspects of imprisonment and maladaptive behavior. As a clinical discipline, the term correctional mental health is often used to be more inclusive of its multiple professional disciplines and settings, which may include jails, state and federal prisons, juvenile or adult detention centers, and residential “halfway” houses, where inmates may live transitionally before leaving prison. Unlike its courtroom counterparts forensic psychology and psychiatry, which focus mainly on legal determinations related to criminal behavior, correctional mental health provides clinical assessment and treatment for incarcerated offenders.

The number of inmates in the United States increased more than fivefold between 1973 and the early twenty-first century, as a “law and order” political climate radically altered initial penal policy efforts at rehabilitation and reintegration of offenders into the community. At the same time public and private mental health resources failed to keep pace with the treatment needs of persons with mental illnesses, increasing the numbers of inmates with untreated mental illness in jails and prisons. Studies indicate that at least 8 to 19 percent of prisoners have significant psychiatric or functional disabilities, with another 15 to 20 percent requiring some form of psychiatric intervention during their incarceration. A recent history of a mental health problem (based on symptoms, diagnosis, or treatment by a mental health professional in the past year) was present in more than half of all prison and jail inmates in the United States. Since the 1970s numerous class-action lawsuits and the appearance of basic standards for correctional mental health care have prompted states to provide a system for identifying and monitoring persons with mental illness severe enough to interfere with their functioning, and for transferring at-risk inmates to treatment settings where specific types of services can be provided by trained mental health staff.

The number and credentials of mental health staff in correctional facilities vary greatly by state and locality. Some facilities have a mental health team consisting of a psychiatrist, psychologist, and social worker consulting together. Where special units for more severely ill inmates have been established, music, art, and occupational therapists, psychiatric nurses, and correctional officers may supplement the treatment team.

Prisons and jails vary greatly in mental health programs and services, as they vary in providing inmates access to the recreation, education, and vocational programs that relieve stress and boredom and can inspire a sense of mastery, positive self-concept, and the possibility (with adequate aftercare and community programs) of creating a prosocial future life. At a minimum, most correctional settings share an emphasis on preventing suicides through brief initial assessments and prompt crisis intervention. Primary treatment modalities may include psychopharmacology, group or individual psychotherapy, substance abuse treatment, and occasionally (especially for selected sex offenders) relapse prevention programs. Some facilities offer all inmates life skills training groups, including meditation and anger management, and groups such as the Houses of Healing program, which survey a range of issues commonly encountered by inmates.

Treatment needs are frequently complex. Substance abuse, homelessness, a physical or sexual abuse history, criminal recidivism, and rule violations in prison are seen more frequently in mentally ill inmates. As the inmate population has grown, so has the list of subpopulations of mentally ill inmates with special treatment needs: women, juvenile offenders, the mentally/developmentally disabled, elderly or dying inmates, sexual offenders, and those with diseases especially prevalent among inmates and the mentally ill, such as HIV and hepatitis C.

Since the 1970s the psychotherapy literature itself has changed its focus from individuals, their behavior within society, and the ways they may be rehabilitated to psychopathologies and their treatment. Critics argue that, in the pursuit of treatments for mental illness that are empirically validated or court mandated, the part of an offender that is syndromally “mad” must be distinguished from that which is morally “bad.” Symptoms, diagnoses, and (especially in assessing sex offenders) actuarial data, in this view, have eclipsed the broader tasks of discovering the cause and context of offenders’ maladaptive behavior and how these fractured individuals, families, and communities may be restored.

However, several factors, including the burgeoning costs of incarceration, have prompted a renewed interest in rehabilitative possibilities. Given high rates of criminal recidivism and illness recurrence when mentally ill inmates return to communities devoid of aftercare and community resources and to avoid a new round of lawsuits, several states are enhancing aftercare programs. “Prison boom” allocations relative to communities’ education, job training, housing, community health care, and mental health budgets are under scrutiny. Research has shown that substance abuse treatment reduces serious crime ten times more than conventional enforcement and fifteen times more than mandatory minimum sentencing. Clear racial and economic disparities (approximately half of prison inmates are black, with an incarceration rate averaging five to seven times that of white prisoners) have prompted more discussion of culturally sensitive styles of therapy but have also raised the question of the social context producing the disparity. Women inmates, who typically have higher rates of mental illness than their male counterparts...
counterparts, are frequently separated from their children, who are often at increased risk of becoming the next generation of inmates with mental illness. Research has highlighted incarceration's chilling effect on marital, parenting, and other relationships as well as the marginal communities from which so many young black males have been transplanted to jails and prisons.

The landmark 1971 Stanford Prison Experiment (SPE) by the psychologist Philip Zimbardo highlights the importance of institutional environments themselves in producing maladaptive behavior. Of twenty-four young men selected as “the most normal and healthiest” following a battery of screening tests, half were randomly assigned the role of prisoner, half the role of guard. After a realistic arrest and booking, each prisoner was brought to the “prison” constructed in the basement of Stanford’s Psychology Department building. Guards wore military-style uniforms and silver-reflecting sunglasses, and prisoners wore a smock with a prison ID number to enhance anonymity. Within days the “guards” were “behaving sadistically … inflicting humiliation and pain and suffering on other young men who had the inferior status of prisoner.” Signs of “emotional breakdown” caused five “inmates” to be removed from the study the first week. Zimbardo had to terminate the two-week experiment after six days, not only because of the violence and degradation by the guards but because he became aware of his own transformation into a “prison superintendent” in addition to his role as principal investigator.

Hans Toch and Kenneth Adams (2002) extended Zimbardo’s “situationist” perspective within an actual prison system by documenting inmates’ maladaptive behavior demographically and cross-sectionally following each inmate’s course over time. They found that disciplinary rates peak by the first six to nine months of incarceration, with the youngest inmates (especially when single, unemployed, and uneducated) having the most difficulty adapting. Where the SPE might predict progressively worsening behavior with more prolonged exposure to “prisonization,” Toch and Adams found instead that inmates typically lead “compromise existences” in prison that allow for behavioral improvement for most inmates over time. Maturation with the passage of time, nonpunitive structure, and participation in even conventional activities could turn attitudes in a prosocial direction. The authors propose that the self-reform happening by chance encounters in prison might be enhanced through a problem-solving (rather than control-oriented) approach in a therapeutic community setting.

Writing in a twenty-five-year retrospective of the SPE and U.S. prison policy, Zimbardo and Craig Haney recall the era of mass incarceration that followed as “a runaway punishment train, driven by political steam and fueled by media-induced fears of crime” (Zimbardo and Haney 1998, p. 712). They conclude with a hope that the nation reconsiders its strategy of seeking and discarding “bad apples”: “While a few bad apples might spoil the barrel (filled with good fruit/people), a barrel filled with vinegar will always transform sweet cucumber into sour pickles—regardless of the best intentions, resilience, and genetic nature of those cucumbers” (Zimbardo 2004, p. 47).

PRISONER’S DILEMMA (ECONOMICS)

The prisoner’s dilemma is a classic example of an environment in which individuals rationally fail to cooperate even though cooperation would make each person better off. A standard formulation is the following: Two men commit a crime and are arrested. The following possible punishments await them. If both men confess, each will receive five years in prison. If neither man confesses, each will receive three years in prison. If one man confesses and the
other does not, the confessor will receive one year in prison whereas the other receives ten.

The two men would receive the lightest sentence if both refused to confess than if neither does so. However, suppose each man is a prisoner in his own separate holding cell, so that it is impossible for the two men to coordinate their behavior. If the prisoners are acting rationally, each will confess. The reason is the following: A person convicted of a crime should confess if it reduces his prison sentence. The complication in each man’s decision is that the consequence of his behavior depends on the behavior of the other man, which he does not know. However, in the prisoner’s dilemma, it turns out that the rational choice for a prisoner is to confess regardless of the behavior of the other prisoner. To see this, if the other prisoner confesses, then confession brings a sentence of five years whereas not confessing brings ten years. If the other prisoner does not confess, then confession brings a sentence of one year whereas not confessing brings three. Thus, confession is a dominant strategy as it is always preferable to the alternative. The two men therefore choose strategies that, although individually rational, are collectively inferior to those they would choose if they could cooperate.

When one considers situations where individuals play a sequence of prisoner’s dilemma games, rational behavior leads to very different outcomes. The reason for this is that for repeated prisoner’s dilemma games, each player will be making a sequence of choices so that the decision to cooperate in one game can depend on the past behavior of the other player. This means that players can reward each other by making choices that depend on the play of their opponent. The existence of noncooperative equilibrium strategies for an infinite repeated prisoner’s dilemma has been shown in many contexts; a classic formulation is explored in Drew Fudenberg and Eric Maskin’s 1986 paper. It is also possible for periods of cooperation to occur in finite sequential games, as described in David Kreps et al.’s 1982 work.

The prisoner’s dilemma is a basic component of any game theory textbook; a particularly insightful treatment may be found in Roger Myerson’s Game Theory (1991). A history that places the prisoner’s dilemma in the context of the development of game theory is William Poundstone’s book Prisoner’s Dilemma (1992).

BIBLIOGRAPHY

**PRISONER’S DILEMMA (PSYCHOLOGY)**

The prisoner’s dilemma game (PDG) is a method of indicating the results of the possible pairings of the cooperative and noncooperative choices of two players. PDG can be illustrated by either of the matrices in Figure 1. With a PDG there are two players, a column player (A) and a row player (B), each of whom has two choices, X or Y, resulting in four possible combinations of choices with each combination yielding a different set of payoffs or outcomes. Payoffs or outcomes can be thought of as rewards or as some index of player satisfaction. The usual convention is that numbers above the diagonal in each cell represent the outcomes for the column player, and numbers below the diagonal in each cell represent the outcomes for the row player. In the example matrices, the numbers, or outcomes, can be thought of as dollars.

Suppose that both players choose X. For the left-hand matrix this combination of choices would result in each player receiving $3. After such a combination of choices, one player, for example the column player, might be tempted to choose Y on the next trial. If the row player continued to choose X, the result would be that the column player’s outcome would increase to $4, but the row player’s outcome would decrease to $1. Following such a result, one can imagine that the row player would shift from X to Y on the next trial, with the result that both players would receive only $2. Such a possibility illustrates the dilemma. Each player can increase his or her outcomes by choosing Y, but if both players are guided by immediate self-interest, both will receive lower outcomes than could have been obtained through cooperation or mutual X choices.

The X choice is usually referred to as a cooperative choice, and the Y choice is sometimes referred to as a competitive choice and sometimes as a defecting choice. Which term is more appropriate depends on whether the Y choice is motivated by greed or by fear. If the Y choice is motivated by greed, or an interest in increasing outcomes, the choice is appropriately referred to as a competitive choice. On the other hand, if the Y choice is motivated by fear, or an interest in minimizing the reduction in outcome resulting from the other player’s Y choice, the Y
choice is appropriately referred to as a defecting choice (a choice to withdraw from cooperation).

According to Matt Ridley, “broadly speaking any situation in which you are tempted to do something, but know it would be a great mistake if everybody did the same thing, is likely to be a prisoner’s dilemma” (1996, pp. 55–56). An everyday example relates to being honest versus cheating. Other examples relate to overwhaling, overfishing, pollution of the air, pollution of the water, and conservation of water during a drought. These latter examples, which may involve more than two people and may provide more than two choices (e.g., how much water to save and not just whether to save or not to save water), are sometimes labeled resource dilemmas and sometimes labeled commons dilemmas. The term commons comes from Garrett Hardin’s (1968, 1993, 1998) description of the potential “tragedy” that could result from overgrazing in a shared, but unmanaged, medieval commons or pasture. Commons dilemmas share with the PDG the assumption that the pursuit of self-interest results in collective detriment. This assumption stands in contrast to Adam Smith’s (1776) marketplace model, which implies that the pursuit of self-interest results in collective benefit. One can regard many political disputes as partially flowing from disagreement regarding which model is more appropriate in a particular situation.

William Poundstone (1992, p. 123) maintains that recognition of the tension between self-interest and the common good was first cast in the form of a two-by-two matrix by two mathematicians at Rand Corporation, Merrill Flood and Melvin Dresher (1952). The matrix was specifically created to provide an empirical test of mathematician John Nash’s concept of an equilibrium point, developed in his 1950 dissertation at Princeton University (see Colman 1995, pp. 58–61; Nasar 1998, pp. 115–122).

For the PDG, the Nash equilibrium is the lower right-hand cell. On the assumption that each player assumes that the other player will follow his or her self-interest, the players should arrive at this mutual-Y cell. Such choices should, furthermore, be stable or in equilibrium, because if either player moves from this cell, he or she will receive a lower outcome. In order to test Nash’s theory, Flood and Dresher had two colleagues in January 1950 play the PDG for one hundred trials. The results indicated that mutual Y choices, the Nash equilibrium, only occurred fourteen times. One player cooperated sixty-eight of one hundred times, and the other player cooperated seventy-eight of one hundred times. Although there was some competition, or defection, clearly the participants did not behave as Nash’s theory predicted.

Subsequently, the Flood and Dresher matrix was labeled the prisoner’s dilemma game by mathematician Albert Tucker, Nash’s adviser at Princeton University. At a talk given to the Psychology Department at Stanford University in 1950, Tucker illustrated the matrix with an anecdote of two prisoners who had been arrested on suspicion of having committed a crime. Each prisoner had a choice of remaining silent (analogous to choosing X) or of giving evidence against the other (analogous to choosing Y). Either prisoner could minimize his sentence by giving
evidence against the other, but when both gave evidence, the prisoners could be convicted of a more serious charge than when both remained silent.

The PDG is sometimes characterized as a matrix meeting two requirements. First, the outcomes in the four cells follow a rank order for the column player from upper right to upper left to lower right to lower left. Note from the left-hand matrix in Figure 1 that the payoffs in these cells are 4, 3, 2, 1. (For the row player, the rank order is from lower left to upper left to lower right to upper right.) Second, the average outcome for the upper-right and lower-left cells is less than the outcome in the upper-left cell. Note that 2.5, the average of 4 and 1, is less than 3. This second requirement guarantees that higher outcomes will be achieved by mutual $X$ choices, rather than by alternating between the lower-left and upper-right cells.

Interdependence theory (Kelley and Thibaut 1978; Kelley et al. 2002) provides a more sophisticated perspective on the PDG. This perspective relies on four concepts that can be illustrated by the left-hand matrix in Figure 1. The first of these is labeled *actor control* (AC) by Harold Kelley and his coauthors, and reflects the direct control that each player has over his or her own outcomes. For the column player, AC is the difference in column averages (the average of 3 and 1, or 2, for the $X$ column versus the average of 4 and 2, or 3, for the $Y$ column). For the row player, AC is the difference in row averages. For both players, AC is 1.

The second concept is labeled *partner control* (PC) by Kelley and his associates, and reflects the direct control that the partner has over actor outcomes. For the column player, PC is the difference in row averages (the average of 3 and 4, or 3.5, for the $X$ row versus the average of 1 and 2, or 1.5, for the $Y$ row). For the row player, PC is the difference in column averages. For both players, PC is 2. Note that AC has a smaller absolute value than PC, and also that an increase in one player’s AC results in a decrease in the partner’s PC. If the column player, for example, increases AC by shifting from $X$ to $Y$, the row player’s PC is decreased. From the perspective of AC and PC alone, the PDG is a matrix in which a small increase in one’s own outcomes results in a large loss in partner outcomes.

The third concept is labeled *joint control* (JC) by Kelley and his coauthors, and reflects the extent to which the players can maximize their outcomes by taking turns, or alternating, their $X$ and $Y$ choices. For both players, JC is the difference in diagonal averages (the average of 3 and 2 versus the average of 4 and 1). For both players, JC is 0; that is, there is no joint control or advantage in alternating $X$ and $Y$ choices. The purpose of the requirement that JC be 0 is similar to the purpose of the above requirement that the average outcome for either column or row player for the upper-right and lower-left cells is less than the outcome in the upper-left cell.

The fourth and final interdependence theory concept is the correspondence between the two players’ outcomes across the four cells. For matrices such as those in Figure 1, in which the players’ outcomes are symmetric, correspondence is indexed by the correlation between the two players’ outcomes across the four cells. For the PDG, the correlation is always negative; that is, in general, as one player’s outcomes increase, the other player’s outcomes decrease.

The correlation between the outcomes for the two players is a mathematical consequence of the AC to PC ratio. For the left-hand matrix, the ratio is 1 to 2 and the correlation is -.80. For the right-hand matrix, the ratio is 3 to 4 and the correlation is -.96. This difference illustrates the point that the PDG is not one matrix, but a family of matrices with differing AC to PC ratios. The importance of this point becomes apparent in view of the interdependence theory assumption that correspondence reflects conflict of interest. As the AC to PC ratio becomes larger, and the correlation more negative, conflict of interest increases. From the perspective of interdependence theory, some PDG situations are more likely than others to lead to conflict.

Research has indicated that when the PDG is played between two groups, each of which is required to make a consensus choice on each trial, there is frequently, but not always, more competition than there is between individuals (see Wildschut et al. [2003] for a statistical summary, or meta-analysis, of published research). This difference, which is labeled a *discontinuity effect*, has been shown to be more evident as correspondence, or the correlation between the individuals’ or groups’ outcomes, becomes more negative.

PRISONS

The prison, which would become a dominant correctional strategy in Western societies, emerged in the late 1700s. Throughout its history, the prison has been used in attempts to achieve various goals of criminal sanctioning: retribution, incapacitation, general and specific deterrence, and rehabilitation. No one theory can account for the historical development and evolution of the prison. Michael Welch, a highly regarded criminologist, makes the observation that correctional ideologies, policies, and practices cannot be understood outside the political, economic, religious, and technological forces that shape them.

HISTORY OF THE PRISON

Forerunners of the more sophisticated models of the prison were workhouses and houses of correction that emerged in western Europe. In the eighteenth century, when European societies were experiencing a dramatic population shift to urban areas due to the breakdown of the feudal order and the Industrial Revolution, these institutions became a mechanism for managing the growing numbers of an urban underclass. The expressed objective of workhouses and houses of correction was to provide vocational training and to instill a work ethic among inmates. However, these institutions functioned more effectively to remove “undesirables” from the community and, most importantly, to provide a cheap source of labor to private industry.

The United States is credited with being most influential in the development and proliferation of the modern prison. A wing of the Walnut Street Jail in Philadelphia (1790–1835) was the first penitentiary. Influenced by the religious ideology of the Pennsylvania Quakers, the penitentiary was designed for the solitary confinement of criminal offenders, a place where they would repent for their sins without the contaminating influences of other prisoners or the community. These objectives were the foundation for the design of the Western State Penitentiary in Pittsburgh and the Eastern State Penitentiary in Philadelphia, opened in 1826 and 1829, respectively. Because it was believed that work would interfere with inmates’ penitence, inmate work was not originally planned or desired by the founders of the penitentiary. However, individual handicraft work (e.g., weaving, woodcarving, leather tooling) was introduced later to ameliorate the negative consequences of solitary confinement and idleness. During the development of the Pennsylvania system, an alternative prison model, the Auburn system, emerged in New York.

The Auburn Prison opened in Auburn, New York, in 1817. The Auburn model incorporated a silent congregate work system, ostensibly through which inmates would learn vocational skills and be instilled with the work ethic. In complete silence, inmates would work in factory-like settings during the day, and return to their cells at night. The goal of the silent system was to prevent the spread of criminogenic values and influences among inmates. Order was maintained through a quasi-militaristic regimen, such as lockstep marching and harsh punishments for rule infractions.

The Auburn system proliferated in the United States at the same time that western European societies modeled their prisons after the Pennsylvania system. Whereas Europeans were compelled by rehabilitative ideals and what they saw as more humane treatment of inmates, the United States was motivated by the low operating costs and profits generated by cheap inmate labor sold to private industry.

Fortresslike industrial factory prisons dominated the penal landscape in the United States until the early twentieth century, when laws were passed, prompted largely by skyrocketing unemployment in the private sector during the Great Depression, restricting prison industry to the manufacture of instate public-use goods. The result of the demise of prison industry was an idle inmate population in which discipline and control, rather than production and vocational rehabilitation, became the primary objective of the prison.

A radical turn in the objectives and nature of the prison in the United States emerged following World War II (1939–1945) with the emergence and dominance of correctional institutions. The expressed goal of correctional institutions was the treatment and rehabilitation of...
inmates. Therapeutic professionals, including physicians, psychologists, educators, and social workers, were charged with diagnosing and treating inmates based on individual needs. Under indeterminate sentencing strategies, parole boards were given more discretionary power to release inmates once they were deemed to be rehabilitated.

The ideals of the correctional system began to unravel in the 1960s, in part due to overcrowding, lack of funding, and a turbulent period of unrest associated with the prisoner rights movement. Despite these systemic circumstances, a neocorporate political climate that exaggerated the failings of the rehabilitation model was successful in garnering public support for a “get tough” approach to crime. The momentum of the movement became most evident in the 1980s when the United States embarked on an “imprisonment binge.” Within a decade, both the prison population and rate of incarceration more than doubled as a result of the proliferation of new federal and state prisons. This trend of expansion continued through the 1990s with the rate of incarceration reaching 491 per 100,000 U.S. citizens in 2005 compared to 139 in 1980. Longer, determinate sentences contributed to this growth, but no single factor is more responsible than the concentration on the arrest and incarceration of illegal drug offenders.

Between 1985 and 1995, over 80 percent of the increase in the federal prison population was due to illegal drug offenses. In 1985, 34 percent of prisoners were incarcerated for drug offenses; by 1995 the proportion was 60 percent. As the state prison populations tripled in the late 1990s, the proportion of inmates incarcerated for drug offenses grew from 9 percent in 1986 to 23 percent by 1995.

IMPACT ON WOMEN AND MINORITIES

The crackdown on drugs had a disproportionate impact on women and minorities, particularly African Americans. There were almost eight times as many female prisoners in 2003 as there were in 1980, and the primary reason for the growth was drug offenses.

Similarly, illegal drug offenses contributed to a much greater extent to the growth of the African American prison population in the latter twentieth century compared to the growth for whites and Hispanics. Welch points out that “African Americans represent 12 percent of the U.S. population, 13 percent of drug users, 35 percent of the arrests for drug possession, 55 percent of convictions for drug possession, and 74 percent of the prison sentences for drug convictions” (2004, p. 439).

PERSPECTIVES ON THE PRISON

The ideals and functions of the prison can be viewed from three broad and competing perspectives: conservative, liberal, and critical. From the conservative perspective, the threat of imprisonment is believed to deter would-be offenders from committing crimes (general deterrence), while the purpose of prisons is to protect society from those who are not deterred (incapacitation), and through this punishment, deter convicted offenders from repeating crimes (specific deterrence). The conservative ideology is based on a fundamental belief that criminal offenders are driven by the choice to engage in criminal behavior and that crime can be controlled through the threat of punishment and the incapacitation of those who are not deterred.

From the liberal perspective, a criminal offense is seen as a result of forces—biological, psychological, or socio-environmental—that influence the behavior. This perspective upholds the rehabilitative ideal that prisons should function to treat and rehabilitate offenders in order that they ultimately may be reintegrated into free society. Under the liberal perspective, scientific inquiry into the etiology of criminal behavior will reveal its underlying causes, and correctional rehabilitation is ideally guided by those etiological factors.

From the critical perspective, the criminal justice system is considered a means of social control that is used by the powerful class over the less powerful. Consistent with Karl Marx’s (1818–1883) writings, criminal behavior is primarily the consequence of the economic order and politics in society. The criminal justice system and prisons, in particular, function to control an economically marginalized population, also defined as a surplus labor pool. Critical criminologists point to historical trends across societies in which correctional populations swell in times of abundant free-market labor and shrink in times of labor shortages. In his compelling book, The Warehouse Prison (2005), John Irwin adopts a critical perspective to describe the economic conditions and resulting marginalized population that spawned the prison expansion in the United States in the late twentieth century.

While the prison remains a dominant strategy aimed at controlling crime and punishing offenders in Western societies, there is a great deal of doubt among scholars that it is an effective strategy beyond retribution and incapacitation. The high recidivism rate of ex-inmates points to the general failure of imprisonment to deter or rehabilitate and, further, may promote a higher level of criminality among those released. With over 90 percent of inmates ultimately returning to free society, this is, or should be, a central concern for social reform.

Prison abolitionists advocate radical reform in the use of incarceration. Vocal prison abolitionists span both ends of the political spectrum. Pointing to the failure of the prison system to reform or deter, and to the swelling prison population, as well as to the evidence and claims
that current practices are racist and classist, abolitionists promote expanded and widespread use of alternatives to incarceration for most offenses and support the decriminalization of certain behaviors, such as drug offenses. With the entrenchment of the prison as a primary means of criminal sanctioning, along with the recent privatization of prisons and of corrections, in general, the abolitionists face powerful ideological and economic barriers.

PRIVACY
One of the main difficulties in assessing the meaning of privacy in the social sciences is that the term usually connotes a normative character. From the liberal defense of privacy as a right that protects individuals from state intervention and abuse, to the feminist critiques that denounce its role in disguising the oppression of women, most definitions of privacy present contrasting perspectives regarding its value or function.

Yet, when approached from the standpoint of ordinary language, privacy describes a certain domain of social practice—spatial, relational, decisional—that is generally expected to be sheltered from public scrutiny. It can be argued then, that privacy also facilitates the emergence of difference and particularity, and nourishes the development of interpersonal relations based on varying degrees of closeness and intimacy (Boling 1996).

The notion of privacy is closely connected to the predicate private, which can be ascribed to places and objects but also to practices, decisions, information, feelings, or—as critic Iris Young synthesizes—any aspect of life from which one has a right to exclude others. Control over access, then, is a central feature of privacy (Gavison 1980). Since the last decades of the twentieth century, concern over the right to privacy, its limits, and the legal measures to protect it has spanned the advances of information technologies and the incursion of the media; regulation over sexuality and the body, reproductive rights, or domestic violence; and issues of family law, such as decisions on childrearing.

In all these discussions, privacy designates a sphere of life that is protected from the influence of what is deemed external, be it state institutions or the public realm more generally. The history of the distinction between the private and public spheres can be traced back to the Greek philosopher Aristotle (384–322 BCE), who conceived the domain of the household and family in opposition to the polis, or public realm of political activity. The divide has since remained a central theoretical notion and was inherited by the social sciences, often resulting in one of the poles viewed as a residual category defined by its opposition and relative subordination to the other. Modern theories of the public sphere, for example, often relegate the private realm to a subsidiary role. Thus, Hannah Arendt (1906–1975) argues that household matters—such as the sustenance and reproduction of life—are necessary preconditions for political life but are not part of it. In a similar vein, Jürgen Habermas sees the family as functioning to prepare individuals to be rational and autonomous actors in the public realm. In both depictions the spheres are clearly distinguished by virtue of their content, the private being equated with the domestic realm where basic necessities of life are satisfied.

The public/private divide is one of the pillars of liberal political theory, where the private is given preeminence as the sphere of individual freedoms. Classical liberal philosophers attribute a quasi-natural quality to the private realm, which is associated to the individual in opposition to the contractual character of society. This becomes evident in John Locke's (1632–1704) natural law arguments restricting the power of the state over private property and the family, or John Stuart Mill's (1806–1873) discussion of privacy as the natural domain of liberty.

Liberalism has long considered privacy a necessary requirement for autonomy, as it provides the adequate milieu to develop the capacity of independent decision making that allows one to lead a self-determined or autonomous life. This argument conveys an implicit spatial understanding of privacy as isolation, or seclusion, straightforwardly demarcating the space of the individual from the outside. However, privacy can conversely be conceived as a condition that allows selective degrees of access and fosters intimacy and relations with others (Schoeman 1992).

Legal perspectives focus on the notion of privacy as a right, questioning if it designates a specific domain not...
provided for by other established rights, such as the right to property or to individual freedoms, or debating whether it is granted by the U.S. Constitution. In the American case, for example, there has been significant discussion since the late nineteenth century concerning the status of privacy as a principle of common law. Whether considered a legal right or a moral principle, however, there is an understanding of the notion of privacy as protecting individuals from unwanted contact with others and intrusion or judgment on personal decisions.

The feminist critique that emerged in the second half of the twentieth century, has consistently challenged the liberal notion that privacy benefits all equally. Through historical and theoretical elaborations, feminists have shown that the conventional distinction between the public and the private spheres is not only naturalized, but also gendered, as the domestic is considered the realm of women and thus deprived of public recognition. The defense of privacy, they argue, serves the purpose of concealing the oppression of women through the appearance of personal choice and intimacy. Feminists deny any particularity of social relationships that happen in private that inherently distinguishes them from those that take place in public, as they are all conditioned by power and hierarchy. Rather, it is the distinction between the private and the public—between a prepolitical or natural sphere and a political one—that performs the ideological role of hiding oppression. Feminist critics have moved to reject the very distinction by stating that even the personal is political (MacKinnon 1989).

Still, several scholars are reluctant to abandon the notion of privacy altogether, and propose to produce a redescription of the concept taking into account the aforementioned critiques. Political theorists like Jean Cohen or Iris Young, for example, argue that privacy does not merely obscure oppressive practices but also enables diversity by protecting from the homogenizing pressure of the public realm and facilitating differences in experience and perspectives. Moreover, the concept is useful to confront domination of women and minorities by preserving a domain of information and decision, which might involve aspects of intimacy, sexuality, the body, or other personal issues. In a similar tone to Ferdinand Schoeman’s suggestions, these arguments draw away from conceiving the private and the public as clearly demarcated spaces, and view them instead as dimensions of social relations present in different spheres of life. Moving away from the normative bend, social sciences might depict privacy as a common practice emerging from and at the same time constituting a shared form of life.

**PRIVATE INTERESTS**

The distinction between public and private interests has deep roots in the Western political tradition, dating back to ancient times. Roman philosopher Marcus Tullius Cicero (106–43 BCE), for example, defined a “republic” as “the property of the people” and argued that the power of the state should be used only to advance the common interests of its citizens. More recently political theorists of widely varying views have argued that government power should only be used to promote the public interest rather than purely private ones.

Seventeenth-century English philosopher John Locke (1632–1704) and later theorists in the liberal social contract tradition contended that the functions of the state should be limited to those that flow from the purposes for which the people consented to be bound by the government. Should government power exceed its assigned purposes and begin to serve the narrow interests of private individuals at the expense of the general public, the latter would no longer be bound by its laws and might even have a right to rebel.
Distinctions between public and private interests have also played an important role in the American political tradition. Like Locke, many of the Founding Fathers believed that the powers of government should be limited to promoting the public interest, as opposed to promoting the selfish parochial interests of individuals or “factions.” The Preamble of the U.S. Constitution reflects this belief, stating that the purpose of the new government is to “provide for the common defense and general welfare,” a phrase repeated in the Constitution’s Spending Clause, which grants Congress the power to raise taxes in order to “provide for the common Defense and General Welfare of the United States.” The phrase “General Welfare” was understood to exclude the possibility of expenditures intended for the sole benefit of particular states and individuals, though there was much disagreement about where the line between “general” and local or private interests should be drawn. In the nineteenth and early twentieth centuries, American courts would periodically invalidate various economic and other regulations on the grounds that they represented “class legislation” intended to benefit narrow interest groups at the expense of the general public.

From ancient times to the present, however, advocates of differing ideologies have disagreed over the question of what interests truly count as “public” and which are merely private. The rise of the modern welfare state accentuated such divisions. Liberals and egalitarians view many redistributive programs as essential to the promotion of the public interest, while libertarians and conservatives see them as wealth transfers to narrow interest groups promoting purely private interests. The concept of the public interest maintains its hold on our imagination in part because we can each define it in a way conducive to our own preferred ideology and self-interest.

**PUBLIC AND PRIVATE GOODS**

Modern economic theory helps to shed light on the distinction between private and public interests through the concept of public and private goods. A public good is characterized by the fact that it is nonrivalrous and nonexclusive. Consumption of the good by one person does not prevent simultaneous consumption by others; nonexclusivity implies that, once the good is produced, it is impossible to exclude anyone in the relevant group from its benefits. A classic example is clean air. One person breathing clean air does not prevent others from enjoying it as well, and once air pollution has been eliminated in a given area, it is impossible to exclude anyone in that territory from benefiting from its removal. Standard public goods theory concludes that, absent government intervention, public goods will tend to be underproduced by the market, since individuals will have little or no incentive to contribute to their production. Instead, many may seek to “free ride” on the efforts of others.

The distinction between public and private goods offers a possible way to draw the elusive line between public and private interests. In theory, the production of a public good is in the interests of everyone in the relevant population, yet underproduction is likely in the absence of government intervention. Thus, the provision of public goods may well be coextensive with the public interest. By contrast, private goods will usually be adequately produced by the market, and so their attempted production by government is likely to advance only private interests, transferring wealth from the general public to narrow interest groups or individual citizens.

However, the production of public goods does not fully capture the concept of the public interest as it is understood by either ordinary citizens or many political theorists. If, for example, the idea of the public interest includes some commitment to distributive justice, wealth transfers that provide only private goods may still be viewed as “public.” Unemployment insurance, old age pensions, and most other welfare state programs provide benefits that economic theory would classify as private goods. Yet, an argument can be made that these programs nonetheless advance the public interest.

As a proxy for the public interest, public goods theory may be overbroad as well as underinclusive. Recent scholarship shows that traditional public goods theory may have been too quick to conclude that public goods will always be underproduced by the market. Scholars have identified several mechanisms by which an optimal level of public goods production can occur even without government intervention. For example, private “planned communities” effectively produce such public goods as security and local pollution control for their residents. It may not be in the public interest for government to try to provide those public goods that are already produced in close to optimal quantities by market mechanisms.

Ultimately, the distinction between public and private interests is very difficult to define because it is more a normative concept than an empirical or theoretical one. Economics and other social sciences can help us understand whether or not a particular goal can be better achieved by the state or by the private sector. But they cannot, in and of themselves, prove that it is in the public interest.

PRIVATE SECTOR

The private sector is the part of a country’s economy that is not controlled directly by the government; it is a term that combines households and businesses in the economy into a single group. The resources of production owned by the private sector are owned in the form of private property. The private sector includes entities such as households and individuals, for-profit enterprises, sole traders, partnerships, corporations, nonprofit-making organizations, charities, and nongovernmental organizations (NGOs). Private sector is contrasted with public sector, which is a comparable term for the governmental sector.

In 2004 the private sector share of gross domestic product (GDP) in current prices in countries of the Organisation of Economic Co-operation and Development was: Australia 85.85 percent, Canada 87.72 percent, Finland 81.48 percent, France 80.73 percent, Germany 85.32 percent, Greece 87.54 percent, Italy 85.68 percent, Japan 84.38 percent, Norway 82.31 percent, Sweden 78.17 percent, the United Kingdom 83.65 percent, and the United States 89.46 percent. In contrast, in developing countries and transition economies the 2004 private sector share of GDP in current prices was lower: the Bahamas 73.29 percent, Botswana 70.50 percent, the Democratic Republic of Congo 69.07 percent, Nicaragua 76.61 percent, South Africa 75.92 percent, Bulgaria 70.36 percent, Croatia 75.36 percent, the Czech Republic 71.98 percent, Georgia 51.44 percent, and the Slovak Republic 75.69 percent (Heston, Summers, and Aten 2006). Dani Rodrik (2000) argues that the reason for the private sector’s low share in developing countries is due to the fact that for governments in low-income countries, creating additional public-sector jobs is administratively easier than establishing an unemployment insurance scheme or subsidizing job security in the private sector.

The distinction between private sector and public sector reflects the two alternative methods of solving the allocation of resources in an economy: markets or government. Markets utilize private ownership of resources—thus the term private sector—for voluntary allocation decisions. In contrast to the public sector, the private sector—with the exception of nonprofit-making organizations, charities, and nongovernmental organizations—mainly searches for profit opportunities. Private companies and organizations produce goods and services in response to supply-and-demand forces in the market, with the final goal of making a profit for the owners and shareholders of the private enterprise.

The private sector plays a key role in accelerating economic growth in market capitalist economies. The private sector is the foundation of the market capitalist economic system. Without the private sector the capitalist market cannot exist, and vice versa. For example, the development of the private sector in transition economies was vital, and the final goal of transition was associated with the private sector being converted into the dominant sector in the economy. In all industrialized or advanced capitalist economies, the absolute and relative size of the private sector is very high. Hence, in a capitalist market economy the private sector is mostly responsible for most of the country’s investments, for the generation of new job opportunities, and for the improvement of standards of living, and it is the source of most technological developments.

The government in market capitalist economies undertakes the following responsibilities to promote and support the private sector:

1. creating proper legal environment for the private sector to function, through private property rights and contract law;
2. introducing customs and tax laws that should encourage private investment;
3. often providing basic infrastructure produced by public enterprises such as water, power, land, transport and communication services, and other necessities;
4. initiating macroeconomic policies and expenditure to increase the demand for the private sector produced goods.

The private sector increases into two ways: through privatization of state-owned enterprises (SOEs) and through the creation and establishment of new firms. In this way, the share of the private sector in the economy grows. Privatization represents the transfer of state-owned assets to private ownership, alongside the creation and fostering of private businesses. Privatization is an alternative way of distributing and choosing the means of generating wealth (Marangos 2004). Consequently, it also may be considered a distribution of political and economic power.
in the economy. The increase of the private sector further implies the abandonment of government control over economic activity, as well as the abandonment of state monopoly in certain sectors. However, as the private sector increases, both income and wealth inequality increase, and intergenerational mobility decreases:

It is true, however, that America was once a place of substantial intergenerational mobility: Sons often did much better than their fathers…. [However,] over the past generation upward mobility has fallen drastically. Very few children of the lower class are making their way to even moderate affluence…. In modern America, it seems, you’re quite likely to stay in the social and economic class into which you were born. (Krugman 2004)

Supporters of the private sector mistrust government-initiated economic activities because they believe that the private sector is both efficient and enterprising. This further increases efficiency because of the increase in macroeconomic productivity due to the adoption of new technology. Critics of the private sector argue that the private sector does not produce public goods, that it creates private monopolies, enhances income and wealth inequality, and discourages intergenerational mobility. Public goods are commodities where the exclusion principle breaks down, and they are nonrivalrous. Such goods include, for example, lighthouses, national defense, police, fire brigades, and traffic lights. In nearly all industrialized or advanced market-capitalist economies, public goods are provided by the government and funded through the collection of state revenues.

PRIVATIZATION

Although privatization is an imprecise term with different meanings in different contexts, it broadly refers to loosening governmental control over public operations. The phenomenon gained prominence in the 1980s and 1990s, when governments in many advanced industrial nations reduced their stake in state-owned industries such as steel, aerospace, railroads, oil, postal services, telecommunications, electricity, gas, and water. Two decades later, the phenomenon diversified into many variants, such as outsourcing, subcontracting, “internal markets,” and public-private partnerships; extends well beyond the industry sectors listed above; and is repeated in the transitional economies of the former Warsaw Pact.

CAUSES AND RATIONALE

In simple economic terms, a small number of goods and services has to be provided publicly. Their defining characteristic is that they cannot be priced and no one can therefore be excluded by price from the benefits they provide—or indeed the disbenefits, since such goods and services may be associated with public ills such as atmospheric pollution and epidemic diseases. Some significant areas of state spending are unpriceable public goods in this sense, including national defense and law and order. Yet there are also policy-determined public goods, or publicly provided private goods, such as medical care, education, pensions, and transport, which could be priced but are not. Depending on the extent to which nations subscribe to the ideals of the Keynesian welfare state, policymakers may decide to provide these goods publicly as a means to bring about greater equality among citizens. On this view, it is deemed unjust if access to (and the quality of) public services such as health care or education depends on an individual’s level of income.

A further cause of the trend toward privatization was that public debt and borrowing requirements in many industrialized nations rose significantly as in the final decades of the twentieth century states found themselves having to foot the bill for burgeoning welfare provisions. Privatization was regarded as a means to cut debts by selling off state-owned assets and by transferring the responsibility for investment to private entities, the management skills and financial acumen of which were expected to create better value for the money for taxpayers.

However, while the newfound prosperity after World War II (1939–1945) led to a continuous expansion of welfare states around the world, this process came to a halt in the 1980s. This was due, first, to the up-and-coming economic paradigm of neoliberalism, which demanded that states relinquish their role in economic affairs so as to restore incentives for economic growth and efficiency. The underlying rationale was that the private sector is more...
efficient in providing these goods because of the disciplining effects of competition, which provides incentives to cut costs and produce goods that people want. Both productive and allocative efficiency were said to improve as a result. Furthermore, increasing processes of economic globalization put states in direct competition to each other for inward investment and provided a further rationale to cut taxes and “roll back” the state.

Finally, although the aforementioned factors triggered privatization predominantly in industrialized nations, governments in developing countries experienced an altogether different cause: the imposition of the principle of conditionality by institutions such as the International Monetary Fund (IMF) and the World Bank. According to the principle of conditionality, access to development aid was made conditional upon the borrower agreeing to meet specific requirements of economic liberalization, resulting in the coerced privatization (and subsequent sale to investors of mostly foreign origin) of many state-owned entities.

**TYPES OF PRIVATIZATION**

The term privatization can refer to (1) assets, as the sale or auctioning off of state property; (2) the organization, as the adaptation of organizational and legal constructs prevalent in the private sector, with the aim of creating autonomous entities unconstrained by political interference; (3) functions, as the abandonment of public functions in favor of market principles and actors; or a combination of the three.

The sale of assets raises problems for public policy if no real contestation from private entrepreneurs is forthcoming—for example, because the privatized entity retains its monopoly position and can therefore restrict output, raise prices, or extract excessive rents. Network utilities such as railways, water, gas, and electricity are particularly vulnerable to such scenarios, because the inherent natural monopoly means that consumers have no choice of network. As a countermeasure, policymakers tend to design complex governance schemes of regulation and deregulation aimed at preventing such exploitation.

The privatization of functions, in turn, is a policy lever that can be introduced at various junctures in the value chain, including the financing, production, provisioning, and operation stages. To use an example, a state may decide to provide publicly a good such as education or health care, but may choose to leave the financing, construction, or operation of schools or hospitals to the private sector, which then rents the finished project back to the government. The separation of production from provision has allowed many forms of such public-private partnerships (PPPs) to emerge, within which responsibili-

...
“no” are the only two possible values is one common type of nominal-level variable. An ordinal-level variable is defined as a variable where (1) the variable can take several possible values and (2) these different values can be placed in some logical numerical order. A variable that measures whether a person (1) strongly agrees, (2) agrees, (3) is indifferent, (4) disagrees, or (5) strongly disagrees with some given statement is a common type of ordinal-level variable.

In order to use ordinary-least-squares regression, there must be a linear relationship between one’s dependent and independent variables. One can see if this linearity requirement has been met by first making a scatterplot with the independent variable on the x-axis and the dependent variable on the y-axis, then calculating a mean for the dependent variable at each value of the independent variable and plotting this series of means on the scatterplot. If the observed series of means looks approximately like a straight line, then the linearity requirement has been met. If not, other regression techniques must be employed.

There are two main reasons why the linearity requirement of ordinary-least-squares regression is seldom met when the dependent variable of interest is nominal or ordinal. First, because there are a limited number of values that the dependent variable can take (as few as two in some cases), any straight line one would try to impose on the scatterplot could, for low and high values of the independent variable, respectively, extend far above or below the possible values that the dependent variable can take. The second reason is best described in the simple case when the dependent variable takes only two possible values. Because the scatterplot in this instance appears as a series of dots dispersed along two parallel horizontal lines, any single line one would try to impose on the scatterplot would cross each of these horizontal lines at only one point. This imposed line would not pass near many of the data points and therefore would not achieve a high degree of fit, as was originally sought. In this situation, a nonlinear function can achieve a much closer fit to the data.

When one’s dependent variable fails to meet the linearity requirement of ordinary-least squares regression, one attempts to mathematically transform the dependent variable so that there is a linear relationship between the independent variable(s) and the transformed dependent variable. Common transformations include taking the natural logarithm or the square root of the dependent variable. When the dependent variable is “limited” and therefore cannot take values above a certain number or below a certain number, the mathematical function one specifies for the transformation must also not be capable of going above or below those same numbers. Probit regression uses the s-shaped cumulative distribution function of the normal distribution to meet this requirement.

Probit regression predicts the probability of seeing a given value of the dependent variable by fitting the available data to a mathematical function from which probabilities can be calculated. Specifically, this function is the inverse of the indefinite integral of the probability density function of the normal (Gaussian) distribution (also known as the “inverse cumulative density function of the normal distribution”). Formally, this function is written as \( \Phi^{-1}(p) = \sqrt{2 \pi} \text{erf}^{-1}(2p - 1) \), where \( \text{erf}^{-1} \) is the inverse error function and \( p \) is the probability of observing a particular outcome on the dependent variable.

Probit regression was first proposed by the entomologist Chester Ittner Bliss (1899–1979) in a 1934 article in *Science* titled “The Method of Probits.” Noting that his dependent variable was too limited to be modeled using ordinary-least-squares regression, Bliss sought to overcome this limitation by transforming his limited dependent variable into a new dependent variable that did not have the same limitations. Using a table derived from the cumulative density function of the normal distribution, Bliss converted the units of his dependent variable into what he called “probability units.” Bliss then used these probability units as his new dependent variable, and fit them to the rest of his data using standard ordinary-least-squares regression. The word *probit* is simply an abbreviation of the phrase “probability unit.”

Probit regression, when it was first developed, provided a powerful yet computationally simple way to model limited dependent variables. It required the use of widely available statistical tables and knowledge of the ordinary-least-squares regression technique. Yet probit regression is not the preferred method for modeling relationships between limited dependent variables and a set of independent variables in the social sciences. According to Adrian Raftery (2001), this is largely because interpreting the dependent variable when it has been transformed into probability units is not easy. Probability units have no common-sense interpretation by themselves, so they must be converted back to simple probabilities before one can effectively convey their meaning in words. A competing and more popular method, logistic regression, can handle the same types of dependent variable but has the additional advantage that the results of the procedure are more easily made interpretable in words.

In terms of binary dependent variables, there is little that distinguishes probit regression from its more popular competitor, logistic regression. Probit regression is simpler computationally than logistic regression, but this advantage is negated through the use of computer software. Ironically, however, the development of generalized linear modeling by John Nelder and R. Wedderburn beginning in 1972 and the creation of computer software for performing the technique re-created a space for probit regres-
sion. Generalized linear modeling was born out of the observation that the many different regression techniques identified at the time were more alike than they were different. Probit regression and logistic regression produced similar predictions for “limited” dependent variables because they were so similar on a general level. But through the process of outlining similarities between the two techniques, key differences were also highlighted. When one has an ordinal-level dependent variable and each category of the dependent variable occurs approximately an equal number of times, logistic regression is most appropriate. When middle categories of the dependent variable occur much more frequently than either low or high categories, probit regression achieves a better degree of fit. Thus, increased computing power and the development of more general statistical models helped to pinpoint a niche for probit regression.

**PROBABILITY**

The concern of empirical social statisticians in matters theoretical is usually limited to troubles regarding choices of random sets with repeatable observables frequencies—meant to test hypotheses that suggest some limitations on these values. (An example is the test of claims regarding discrimination.) As many statistical observations are hardly ever repeated, a huge literature discusses the question of how representative observed sets are: Is an observed distribution characteristic of the whole population, or is it due to an accidentally great deviation from it?

Diverse examinations of the likelihood of a freak accident are calculated, all made on the basis of assumptions, often reasonable but at times highly question begging. For example, social statisticians seldom notice that the calculations take empirical finds as crucial tests between hypotheses. They specify single hypotheses without troubling themselves to consider the hypotheses the calculations take as the default options. Most social statisticians are ignorant of the mathematical intricacies involved and of the fierce debates among top experts in the field as to what exactly these calculations mean. The long and the short of it is this: How representative is the sample? This question translates into a question of the sample’s randomness.

Critics often suggest that randomness is wanting because the criterion of the choice of the sample introduces bias. The standard example is in biology. The use of laboratory animals introduces bias and renders some tests worse than useless. In social research it is the use of telephone books for the selection of random telephone numbers, in aversion of the fact that in some cases the choice of people with telephones introduces bias. The best way to handle bias is to repeat the test with a new sample using different criteria. In some cases tests for the randomness of a sample may comprise random selections from the existing sample.

The most popular computer program for social statisticians, SPSS (originally Statistical Package for the Social Sciences), warns users against correlating everything in sight, because such an approach is sure to yield some useless (because unrepeatable) results. Common sense reduces such risks, but no method is foolproof. It is therefore always advisable to be wary of computer-generated numbers. To this end, it may be useful to comprehend the general ideas behind the statistics.

The term *probability* is open to different readings. Some of these may be subject to the mathematical calculus of probability (see below) and some not. Methodologists are most concerned with two of these readings, only one of which obeys this calculus. (Many insist that this need not be so.) In one sense probability, especially betting, is a matter of guesses. In another sense probability is the plausibility of a conjecture, as in the common assertion, “What you say is probable.” Can different people propose competing probable views? To deny this is to dismiss without debate the views of peers who reject what seems plausible. This is inadvisable, at least in a democracy. Suppose, then, that it is possible for competing views to be probable. Since the calculus of probability ascribes to the probable the numerical value of more than one-half and considers the sum of probabilities of all alternatives to be at most unity, the probable in this sense defies this calculus.

Many methodologists deem this argument misleading. It fails for scientific ideas, they say, where such cases
are a priori impossible. Not so: When two new theories compete, researchers who find both plausible seek facts that will tip the scale against one of them. In the light of such experiments, theories do gain probability in a sense that defies the mathematical theory of probability. Proof: The mathematical theory will render more probable the theory that comes closer to existing information, yet such theories are implausible. Plausibility goes to an imaginative theory that looks implausible at first and then gains support from new information. The calculus distinctly does not differentiate between information that was known before the theory was invented and the information that the theory reveals. End of proof.

Theoretical learning results from the wish to understand observed regularities. Probability is the study of luck. With no foreknowledge of the fates of individuals, we know that ensembles have a percentage of lucky members, a percentage that improves or declines with the institution of precaution or carelessness, respectively. The simplest ensemble is that of tosses of a coin. Unable to predict single outcomes, we can predict their ratio—a number between 0 and 1. We tend to assume that this ratio is one-half. Not so, because a tossed coin with one side heavier than the other will more often fall on the heavy side: It is biased or unfair. All tossed coins turn out to have a constant ratio of heads turning up; this ratio is the probability for heads. Given a coin that we have not tested, we cannot know whether the probability of heads for it is one-half, but we take it for granted that it is a fixed ratio. Moreover as most coins that we use are fair, we tend naïvely to assume that one that we have not tested is fair. Some gamblers misuse this naïveté regularly.

Some say that in the absence of prior information about a coin, we have to consider it fair. Of course they say this because they speak of probability in a different sense—subjective (see below). Thus even when limiting our discourse to luck, we understand probability in different ways.

The mathematical theory of probability considers in the abstract a set of items with numerical values in a manner that follows certain intuitive axioms. These are basic equations that assign to every ordered pair \(a\) and \(b\) of these items a number called \(p(a, b)\) (the conditional probability of \(a\) given \(b\)): \(p(a, b) = r\) \(0 \leq r \leq 1\).

The axioms of probability relate these numbers and items. Instead of going into the detail of the axioms, most textbooks, including most mathematically powerful ones, use examples, such as a series of outcomes in tosses of a coin, throws of a die, or pulls of a playing card out of a pack. These examples legitimately stand for the major theorems of the calculus, provided that the rule of equal probability that they usually exhibit is not generalized to allow for marked cards or biased or unfair coins and dice.

The troubled discussions about probability that occurred at the turn of the nineteenth century disappeared with the realization that equiprobability is only one possible probability distribution among many. The alternative ways to assign equiprobability seem problematic only because of erroneous methodology. Quantum theory beautifully illustrates the freedom of assigning these. The philosopher Rudolf Carnap (1891–1970), for example, tried to use one quantum probability distribution in his theory of subjective probability (1962). Deviations from traditional rules about probability are hypotheses to be tested like any other. The identification of probability with plausibility plays havoc, as tests may grant such theories plausibility. Giving up this identification dispels such troubles. The axioms of probability, then, concern measures of possibilities, and assuming any distribution is thus conjectural: The more-possible items receive a higher degree of probability, with impossibility as probability 0 and necessity as probability 1. Probability can be a measure of the possibility of success in betting, and it can be the betting success rate; it can also be more than that. This is why the axioms of probability should apply to an unspecified set of uninterpreted items.

The axioms demand, then, that every item \(a\) has a complement \(b\), given \(c\); if for some \(d\), \(p(d, c) = 1\), then \(p(a, c) + p(b, c) = 1\). Obviously otherwise \(p(a, c) + p(b, c) = 2\). Similarly for every \(a\) and \(b\), there is an item \(c\) that is their conjunction: \(p(ab, d) = p(c, d)\) for every \(d\). It turns out, as Karl Popper (1902–1994) has proved, that these rules abide by Boolean algebra (1968). The heart of probability theory is the multiplication theorem, the feel for which is central to the general feel for probability. It is intuitively obvious that probability is a monotone function: for every three items, \(p(ab, c) \leq p(a, c)\); and \(p(ab, c) = p(a, bc)\) times \(p(b, c)\). For \(c\) that may be ignored (it may be understood as the universal condition, as the condition that always holds in the system under study), we may write \(p(a)\) for \(p(a, c)\). The probabilities depending on it are known as absolute probabilities. The multiplication law for absolute probabilities, then, is \(p(ab) = p(a, b)\) times \(p(b)\). And if \(p(b) = 0\), then obviously \(p(a, b) = p(ab)\) divided by \(p(b)\). This makes it obvious that conditional probability is logically prior to absolute probability, since items that have zero probability appear in probability considerations of all sorts (Rényi 1970; Popper 1968).

One of the most popular reasons for the subjective view of probability is the theory of errors, the assumption that random errors of measurement of some given quantity cancel each other, so the most reliable hypothesis about that quantity is that it is the average of the many measurements of it. This makes probability appear as reliability (of measurements). Consider then the hypothesis that reliability of measurements follows the axioms of the
theory of probability. If this reliability is measurable by the reliance that people ascribe to measurements, then this hypothesis is empirically easily refuted: People prefer impressions to averages. This is not the case with researchers, however, as they assume errors to be random. Otherwise they are ready to change their minds. Hence, the errors in question are not errors of reliability. Moreover the same formula applies to acts, such as shooting at a target, that have nothing to do with reliability. Consider the correction of a gun fixed on a gun rest, aimed at a target, and hitting the target on average at a point that is not its center. The most important aspect of this kind of exercise is that it is repeatable. Otherwise it is pointless. (The same holds for the way astronomers eliminate random errors due to atmospheric interferences.) The demand for repeatability clearly eliminates the problem of credence. Those who refuse to work on repeatable experience are invited to test it afresh. Repeatable situations with deviations are particularly important for plotting the graph of the random differences between each hit and the center of the target. These random deviations are errors in the sense of distractions, not in the sense of observers negligently making mistakes. The error graph is in the famous bell shape (achieved when the sample grows infinitely to cover all possible deviations); the smaller the errors, the thinner the bell. This is known as dispersion, and it is essential for the study of populations subject to diverse random deviations. In physics the expression of the wish to find sharp spectral lines is the effort to reduce random interferences in the process of radiation (heat).

Historically the strongest reason for subjective probability was provided by the Marquis de Laplace (1749–1827) and later was endorsed by Albert Einstein (1879–1955): Facts are predetermined, and probability is due to ignorance. The opposite view is that randomness is objective. The chief argument here is that the assumption of randomness is essential for almost all successful application of the calculus of probability (the exception being its application to number theory). The subjectivist view of randomness as mere ignorance leads to the defunct assumption of equiprobability. Sophisticated subjectivists admit this but take it as a challenge, relying on another, more convincing reason to view probability as subjective and randomness as ignorance. It rests on a theorem named after Thomas Bayes (1702–1761). (This is why subjectivism is often called Bayesianism.)

Bayes’s theorem concerns inverse probabilities. It is the formula that enables the move from the value of \( p(e, h) \) (of empirical data given a theory) to the value of \( p(h, e) \) (of a theory given empirical data), from the likelihood of an effect given one of its causes to the likelihood that a given cause is responsible for the effect at hand. This formula is a theorem that is easily deducible from the multiplication law, provided all relevant probabilities are given. This of course is an objectivist proviso; viewed subjectively, however, these provisos are convictions. This leads back to the defunct rule of equiprobability. Moreover, the most important theorem of probability theory, the law of large numbers, is not given to the subjectivist interpretation. It says that any option, however improbable, will occur in a sufficiently large collection, although the less probable the option, the less frequent it will be.

**PROBABILITY, LIMITS IN**

The terms *limits in probability* and *probability limits* are encountered in the field of Bayesian inference and in the

Joseph Agassi
field of asymptotic theory; however, their meanings are applied differently in each of these two areas. In terms of popularity, probability limits as applied to Bayesian inferences seems to appear more frequently in current literature, especially in applied statistical sciences.

PROBABILITY LIMITS IN BAYESIAN STATISTICS

In Bayesian inference, or Bayesian statistics, probability limits are also referred to as “credibility limits.” Probability limits are the upper and lower end-points of the probability (or credible) interval that has a specified (posterior) probability (e.g., 95% or 99%) of containing the true value of a population parameter. Probability limits are used when the parameter is considered as the realization of a random variable with given prior distribution. As the distribution is presumably assessed prior to sample evidence, such distribution is called a “prior distribution.” In classical inference, the parameter is considered to be an unknown constant, and then confidence limits are applied. Both upper and lower probability limits reflect not only prior information, but also sample information; therefore they are random statistics.

Confidence limits are the upper and lower end-points of an interval around a parameter estimate, such that if an experiment were repeated an infinite number of times, in the specified percentage (usually 95% or 99%) of trials the interval generated would contain the true value of the parameter. Confidence limits may be calculated using asymptotic (normal approximation) or exact methods. Both upper and lower confidence limits are obtained (purely) from sample data, so they are also a realization of random statistics.

Bayesian inference or Bayesian statistics is based on the theory of subjective probability. A formal Bayesian analysis leads to probabilistic assessments of the object of uncertainty. For instance, a Bayesian inference or Bayesian statistics, the parameter \( \lambda \) is considered to be a random variable, so a bold \( \lambda \) is used in the next sentence. Now suppose that a random sample of size \( n \) has been drawn from the underlying Poisson distribution. Let \( X = (X_1, X_2, \ldots, X_n) \), then the joint conditional probability density function (pdf) of \( X \) given \( \lambda = \lambda \), is

\[
L(x|\lambda) = \frac{\lambda^{x_1}e^{-\lambda}}{x_1!} \cdot \frac{\lambda^{x_2}e^{-\lambda}}{x_2!} \cdot \ldots \cdot \frac{\lambda^{x_n}e^{-\lambda}}{x_n!},
\]

\( x_i = 0, 1, 2, \ldots, n \).

The prior pdf is

\[
b(\lambda) = \frac{\lambda^{\alpha-1}e^{-\lambda/\beta}}{\Gamma(\alpha)\beta^\alpha}, \quad 0 < \lambda < \infty.
\]

Hence, the joint mixed continuous and discrete probability function is given by

\[
L(x|\lambda)b(\lambda) = \left[ \frac{\lambda^{x_1}e^{-\lambda}}{x_1!} \cdot \frac{\lambda^{x_2}e^{-\lambda}}{x_2!} \cdot \ldots \cdot \frac{\lambda^{x_n}e^{-\lambda}}{x_n!} \right] \left[ \frac{\lambda^{\alpha-1}e^{-\lambda/\beta}}{\Gamma(\alpha)\beta^\alpha} \right]
\]

\[
= \frac{\lambda^{\alpha-1+\sum x_i}e^{-\lambda(\alpha+1)/\beta}}{\Gamma(\alpha)\beta^\alpha x_1!x_2!\ldots x_n!},
\]

provided that \( x_i = 0, 1, 2, \ldots, n \) with 0 < \( \lambda \) < \( \infty \), and is equal to zero elsewhere. Then the marginal distribution of the sample is

\[
G(x, \lambda) = \int_0^\infty \frac{\lambda^{\alpha-1+\sum x_i}e^{-\lambda(\alpha+1)/\beta}}{x_1!x_2!\ldots x_n!\Gamma(\alpha)\beta^\alpha} d\lambda
\]

\[
= \frac{\Gamma(\alpha + \sum x_i)\beta/\beta(\alpha+1)}{\Gamma(\alpha)\beta^\alpha x_1!x_2!\ldots x_n!}.
\]

Suppose that the observations are \( x = (x_1, x_2, \ldots, x_n) \). Finally, the posterior pdf of \( \lambda \), given \( X = x \), is

Finding Bayesian Probability Limits There is some flexibility in choosing the credible limits from a given probability distribution for the parameter. Examples include: choosing the narrowest probability interval that, for a unimodal distribution, will involve choosing those values of highest probability density (highest posterior density credible limits); choosing the probability interval where the probability of being below the interval is as likely as being above it (the interval will contain the median); and choosing the probability interval that has the mean as its central point. The following is an illustration of finding probability limits using the second method.

In a problem of making inferences about the mean \( \mu \) of a Poisson distribution, the prior distribution is given as a \( \Gamma(\alpha, \beta) \) distribution with known \( \alpha \) and \( \beta \). In Bayesian statistics, the parameter \( \lambda \) is considered to be a random variable, so a bold \( \lambda \) is used in the next sentence. Now suppose that a random sample of size \( n \) has been drawn from the underlying Poisson distribution. Let \( X = (X_1, X_2, \ldots, X_n) \), then the joint conditional probability density function (pdf) of \( X \) given \( \lambda = \lambda \), is
\[ k(x, \lambda) = \frac{L(x|\lambda) b(\lambda)}{G(x, \lambda)} = \frac{\lambda^{n-1} e^{-\lambda} \lambda^{x_1} e^{-\lambda (n\beta + 1)} \beta}{\Gamma(\alpha + \sum_i x_i) \beta^{(n\beta + 1)} \alpha^\alpha \beta^\beta}, \]

provided that \( x_i = 0, 1, 2, \ldots, i = 1, 2, \ldots, n \) with \( 0 < \lambda < \infty \), and is equal to zero elsewhere. This posterior pdf is also a gamma distribution with parameters \( \alpha^* = \alpha + \sum_i x_i \), \( \beta^* = \beta(n\beta + 1) \).

Notice that the posterior pdf reflects both prior information carried by \((\alpha, \beta)\) and the sample information \( \sum_i x_i \).

To obtain a credible interval, note that the posterior distribution of \( \frac{2(n\beta + 1)}{\beta} \lambda \) is \( \chi^2(2\alpha + \sum_i x_i) \). Based on this, the following interval is a \((1 - \alpha)\) 100 percent credible interval for \( \lambda \):

\[
\left( \frac{2(n\beta + 1)}{\beta} \chi_{1 - \alpha/2}(2(\alpha + \sum_i x_i)), \frac{2(n\beta + 1)}{\beta} \chi_{\alpha/2}(2(\alpha + \sum_i x_i)) \right)
\]

where \( \chi_{1 - \alpha/2}(2(\alpha + \sum_i x_i)) \) and \( \chi_{\alpha/2}(2(\alpha + \sum_i x_i)) \) are the lower and upper quantiles of a \( \chi^2 \) distribution with \( 2(\alpha + \sum_i x_i) \) degrees of freedom. Then, \( \frac{2(n\beta + 1)}{\beta} \chi_{1 - \alpha/2}(2(\alpha + \sum_i x_i)) \) and \( \frac{2(n\beta + 1)}{\beta} \chi_{\alpha/2}(2(\alpha + \sum_i x_i)) \) are \((1 - \alpha)\) 100 percent probability limits of \( \lambda \).

**Relationship to Confidence Limits** For the example above, the confidence limits can be obtained by applying the distribution of sample sum \( \sum^\alpha x_i \). Note that the distribution of \( \sum^\alpha x_i \) is also a Poisson distribution with \( \lambda^* = n\lambda \). For the lower limit of a \((1 - \alpha)\) 100 percent confidence interval for \( \lambda \) can be selected so that

\[
\sum^\alpha_{i=0} \frac{(n\lambda)^i e^{-n\lambda}}{i!} = \frac{\alpha}{2};
\]

and the upper limit of a \((1 - \alpha)\) 100 percent confidence interval for \( \lambda \) can be solved by

\[
\sum^\alpha_{i=0} \frac{(n\lambda)^i e^{-n\lambda}}{i!} = \frac{\alpha}{2}.
\]

In general, equations such as (2) and (3) are impossible to solve algebraically. The solutions can be obtained using a search procedure on a computer.

The asymptotic confidence limits for \( \lambda \) may be obtained by

\[
P\left( \frac{\sum^\alpha x_i - n\lambda}{\sqrt{n\lambda}} \leq z_{\alpha/2} \right) = 1 - \alpha.
\]

So, the \((1 - \alpha)\) 100 percent confidence limits for \( \lambda \) are

\[
\left( \frac{2\sum^\alpha x_i + z^2_{\alpha/2}}{2n} \pm \frac{1}{n} \sqrt{\frac{2\sum^\alpha x_i + z^2_{\alpha/2}}{2} - (\sum^\alpha x_i)^2} \right).
\]

In addition, the further approximation for the confidence limits for \( \lambda \) using standard error of \( \frac{1}{n} \sum^\alpha x_i \) are

\[
\frac{1}{n} \sum^\alpha x_i \pm z_{\alpha/2} \sqrt{\frac{\sum^\alpha x_i}{n}}.
\]

Compare (1) to (4) or (5); they are quite different. Probability limits are obtained by a combination of subjective knowledge of \( \lambda \) and the objective information from the sample data whereas confidence limits only contain pure objective information.

There are situations in which the confidence limits and credible limits are numerically identical. For example, if \( \mu \) is a location parameter of a normal distribution, and the prior for \( \mu \) is uniform, then the 95 percent central confidence limits are identical to the 95 percent highest density credible limits.

**PROBABILITY LIMITS IN ASYMPTOTIC THEORY**

For a sequence of random variables \( \{X_n\} \), if there exists a real number \( c \) such that for every small positive number \( \epsilon \) the probability that the absolute difference between \( X_n \) and \( c \) is less than \( \epsilon \) has the limit of 1 when \( n \to \infty \), namely,

\[
\lim_{n \to \infty} P|X_n - c| \leq \epsilon = 1,
\]

then we say that \( \{X_n\} \) converges in probability to constant \( c \), and \( c \) is called the probability limit of \( \{X_n\} \) (White 1984). See Simons (1971) for how to identify probability limits.

For example, if the average of \( n \) independent, identi
cally distributed random variables \( Y_i \), \( i = 1, \ldots, n \), with a common mean, \( \mu \), is given by \( \bar{Y} = \frac{1}{n} \sum_{i=0}^n Y_i \), then as \( n \to \infty \), \( \bar{Y} \) converges to \( \mu \) in probability. The common mean, \( \mu \), of the random variables \( Y_i \) is the probability limit of the sequence of random variables \( \{Y_i\} \). This result is known as the weak law of large numbers. In the context of estimation, we also call \( \bar{Y} \) a (weakly) consistent sequence of estimators for \( \mu \).

More generally, convergence in probability means that a sequence of random variables \( \{X_n\} \) converges to a
random variable $X$, which is not necessarily a constant. It has not been observed that “probability limit” is used, for this general case, as a limiting random variable.

In probability theory there exist several different notions of convergence of random variables. The convergence of sequences of random variables to some limiting random variable (illustrated below) is an important concept in probability theory, and in its applications to statistics and stochastic processes. The following section presents a brief overview of the various modes of convergence of a random variable sequence, and the relationships between them (for greater detail, see Parzen 1960).

**Modes of Convergence of a Random Variable Sequence**

Suppose that $\{F_n\}$ is a sequence of cumulative distribution functions corresponding to random variables $\{X_n\}$, and that $F$ is a distribution function corresponding to a random variable $X$. We say that the sequence $\{X_n\}$ converges to $X$ in distribution, if $\lim_{n \to \infty} F_n(a) = F(a)$ for every real number $a$ at which $F$ is continuous. This is the notion of convergence used in the central limit theorem.

A sequence of random variables $\{X_n\}$ is called convergent in probability to a random variable $X$ if for any $\varepsilon > 0$,

$$\lim_{n \to \infty} P(|X_n - X| \leq \varepsilon) = 1.$$  

Convergence in probability is the notion of convergence used in the weak law of large numbers.

A sequence of random variables $\{X_n\}$ is called convergent in mean square to a random variable $X$ if

$$\lim_{n \to \infty} E[(X_n - X)^2] = 0.$$  

More generally, for any $p > 0$, a sequence of random variables $\{X_n\}$ is called convergent in $p$-mean to a random variable $X$ if

$$\lim_{n \to \infty} E[(X_n - X)^p] = 0.$$  

A sequence of random variables $\{X_n\}$ is called convergent almost surely to a random variable $X$ if

$$P\left(\lim_{n \to \infty} X_n = X\right) = 1.$$  

A sequence of random variables $\{X_n\}$ is called convergent surely to a random variable $X$ if $\lim_{n \to \infty} X_n = X$.

**Relationships between Various Modes of Convergence**

There are a few important connections between these modes of convergence. Convergence in distribution is the weakest form of convergence, and is in fact sometimes called weak convergence. It does not, in general, imply any other mode of convergence; however, convergence in distribution is implied by all other modes of convergence mentioned herein, except convergence in distribution. If $\{X_n\}$ converges in distribution to a constant $c$, then $\{X_n\}$ converges in probability to $c$. Namely, when the limit (constant) in probability exists, the convergence in probability is equivalent to the convergence in distribution. Both convergence in mean square and almost sure convergence imply convergence in both distribution and probability. However, the inverse is not commonly true; convergence in mean square does not imply almost sure convergence, and vice versa.

**LEgITIMATE CRITICISMS**

In order to avoid possible confusion in using the term probability limits in these two different contexts discussed above, we suggest using “credible limits” for Bayesian probability limits, and using “a limit that … converges to in probability” in reference to the limit of a sequence of random variables that is convergent in probability when discussing asymptotic theory.

**Xiaojian Xu**

**PROBABILITY, OBJECTIVE**

**SEE** Probability.

**PROBABILITY, SUBJECTIVE**

The subjective or personalist theory of probability views probability as the likelihood that a particular individual attaches to the occurrence of an event or the truth of a
Probability, Subjective

proposition, rather than as the frequency with which a particular observation would occur in a long sequence of repetitions.

In his *Treatise on Probability*, published in 1921, but written as a Cambridge fellowship dissertation before World War I (1914–1918), John Maynard Keynes (1883–1946) distinguished a probability distribution over possible outcomes from an individual’s degree of belief that a particular probability distribution was in fact the true probability distribution, with the degree of belief reflecting the weight of available, relevant evidence. Keynes viewed probability as an objective relation that would be perceived the same way by any rational person with the same information. Émile Borel (1871–1956) and Frank P. Ramsey (1903–1930) responded by arguing for the more subjective interpretation that a person can have any degree of belief in any given statement on any evidence, and those beliefs will still be consistent and coherent, provided only that the person’s subjective probabilities attached to all possible outcomes sum to one and are bounded by zero and one, with a probability of $p$ attached to statement or event $S$ implying a probability of $1−p$ attached to the denial of $S$. (The relevant essays by Borel and Ramsey are reprinted in Kyburg and Smokler [1964]; see also Bruno de Finetti’s 1937 monograph and Bernard O. Koopman’s 1940 article in that volume.) In his memorial article on his friend Ramsey, Keynes accepted Ramsey’s criticism on the issue of the subjectivity of degrees of belief.

Like Frank Knight’s (1885–1972) *Risk, Uncertainty, and Profit* (1921), Keynes distinguished between risk (where outcomes are random, but the probability distribution of outcomes is known) and uncertainty (where the probability distribution is not known, and even a complete list of possible outcomes may not be possible). Risk is insurable, but uncertainty is not. Knight saw entrepreneurial profit as the reward for bearing uncertainty. Knight (1921, pp. 250-251) held that insurance was feasible only in situations with little objective data provided that professionals in the relevant field could make “conservative and competent” estimates (even if insurance was imperfect in such situations because of moral hazard), but that there remained some uncertainty that was “uninsurable (because unmeasurable and this because unclassifiable),” when it was not possible for businessmen to even list all the possible outcomes. According to Keynes (1921), not all degrees of belief are numerically measurable or even comparable. Writing on long-period expectations in chapter 12 of his *General Theory of Employment, Interest, and Money* (1936), Keynes invoked fundamental, uninsurable uncertainty about the prospects of another world war, technological breakthroughs, or the position of property owners in the future social order to explain the volatility of private investment spending; expectations of the profitability of investment projects are guesses about an unknown and unknowable future, and are subject to drastic revision as scraps of new information become available. Under nonergodic conditions of true uncertainty, past observed frequencies are highly imperfect guides to future events, and a universe of discoverable regularities that can be expected to continue is a misleading analogy (Davidson 1991). Other chapters of Keynes’s *General Theory*, however, proceeded as though discoverable regularities exist.

Leonard J. Savage (1917–1971) and I. J. Good developed the personalist view of probability advanced by Ramsey, de Finetti, and Koopman, and explored its implications for statistics. In this view, probability is no more than an index of a person’s degree of belief in a statement (or in the occurrence of a future event), and reflects the limitations of a person’s information, which may or may not reflect any inherent randomness in the world. Good and Savage emphasized Thomas Bayes’s (d. 1761) theorem or rule as the way to update one’s belief in the probability of statement $S$ in light of some observed data. The probability that the data is observed and that $S$ is true can be expressed either as the probability of the data being observed given that $S$ is true multiplied by the prior probability that $S$ is true, $Pr(\text{data}|S)Pr(S)$, or as the probability of the data being observed multiplied by the probability of $S$ being true given that the data have been observed, $Pr(\text{data})Pr(S|\text{data})$. The posterior probability that $S$ is true given that the data have been observed, $Pr(S|\text{data})$, can be solved for as $Pr(\text{data}|S)Pr(S)/Pr(\text{data})$. The approach pioneered by Good and Savage is known as Bayesianism (see Joyce 2004) and views rational behavior as the maximization of subjective expected utility (with expected utility being linear in probabilities) subject to probabilistic beliefs that have been updated according to Bayes’s theorem. To the Bayesian, there is no distinction between uncertainty and risk: using available evidence in forming updated, posterior probabilities (over all possible, mutually exclusive outcomes, with “any other outcome” as one of the possibilities, so that the list is exhaustive) does not presume that a true, objective probability distribution will ever be achieved.

Various paradoxes, such as the Allais paradox and Ellsberg paradox, have been observed, in which people make choices in ways that violate Savage’s axioms for rationality in the sense of maximization of expected utility given coherent and consistent beliefs about probabilities (Machina [1987] and the extensive references given there, as well as Jallais and Pradier [2005]). Experiments conducted by the psychologists Daniel Kahneman and Amos Tversky (1937–1996), for which Kahneman received the 2002 Nobel Prize in economics, revealed framing effects, in which choices made by subjects depend on how questions are put: in particular, someone may
assign probability \( p \) to a statement (or event) \( S \), yet assign some probability other than \( 1 - p \) to not-\( S \).

Daniel Ellsberg (1961) showed experimental subjects two urns, one with fifty red balls and fifty black balls and the other with one hundred balls, an unknown number red and the rest black. Offered a prize for drawing a red ball, subjects strictly preferred to draw from the first urn, yet offered a prize for drawing a black ball, they again strictly preferred to draw from the first urn, a result not consistent with any subjective probability assigned to drawing a red ball from the second urn. Several commentators have interpreted such results as displaying aversion to uncertainty or ambiguity. Savage responded to Maurice Allais’s counterexample (in which Savage himself responded to twenty questions from Allais in ways that violated Savage’s axioms) by reinterpreting his axioms as a normative theory, which should convince anyone to whom it was explained suitably, rather than as a positive theory of rational behavior (Jallais and Pradier 2005). Peter Fishburn, David Schmeidler, and Robert Sugden, among others, have dealt with the observed paradoxes of choices involving subjective probability by generalizing expected utility theory by dropping the standard additivity or compounding rules of probability theory (Machina 1987).

**BIBLIOGRAPHY**

**PROBABILITY DISTRIBUTIONS**

The fundamental notion in statistics is that of a group (aggregate), which is usually called a population. This denotes a collection of objects, whether animate or inanimate, for example, a population of humans, of plants, of mistakes in reading a scale, and so on. The science of statistics deals with properties of populations, or more precisely, with the data obtained by counting or measuring properties of populations of natural phenomena. Natural phenomena include various happenings of the external world, whether human or not.

Consider a population of members each of which bears some numerical value of a variable (variate), for example, a population of men with measured height. Here the variable is the height of men. We thus have a population of variates (which can be discontinuous [discrete] or continuous). In the continuous case, the number of members possessing a variate value that falls into a given interval of the variate values is called the frequency in that interval. Finally, the manner in which the frequencies are distributed over the intervals is called the frequency distribution (or simply distribution).

To everything in social science there is a distribution. From the characteristics of persons and the aggregates they form—health and wealth, city size and resource endowment, happiness and social harmony—to the characteristics of myriad other entities—stock performance, volatility of money, the number of words in a language—distributions both summarize the characteristics and describe their operation.

Moreover, there are distributions for every kind of variable: continuous or discrete; defined on a support that may be any subset of numbers (positive half-line, full line, positive integers, etc.); displaying a great variety of shapes; symmetric or asymmetric; with zero, one, or many peaks; skewed to the left or the right; possessing one or several modes; and so on. As a rule, continuous distributions are specified by mathematical functions.

Functions of variables and combinations (mixtures) of variables generate new variables whose distributions show the imprint of the input distributions and their
Probability Distributions

interrelations. Because approximation of a variable’s distribution unlocks many doors—in theoretical analysis, where distributions are a prime tool for forecasting and prediction, and in empirical analysis, where distributions usually serve to represent the unobservables—detailed compilations of distributions are a necessary part of the social scientist’s toolkit.

For introduction and comprehensive exposition, see Stuart and Ord (1994), Dwass (1970), and Tsokos (1972), and for rather encyclopedic coverage the volumes in Johnson and Kotz’s series, Distributions in Statistics, and their revisions (e.g., Johnson, Kotz, and Balakrishnan 1994). The handbook by Evans, Hastings, and Peacock (2000) is an appropriate and valuable source for initial study.

ASSOCIATED FUNCTIONS

A variety of mathematical functions are associated with mathematically specified distributions. The most basic is the distribution function, also known as the cumulative distribution function (cdf). The distribution function may be defined as a mathematical expression that describes the probability that a system (consisting of several components) will take a specific numerical value or set of values (such a varying system is designated as a “random variable” and usually denoted by capital X, Y, or Z). The description of a system may involve other quantities, and the distribution function may take into account some (or all) of them. In the case of a system with one variable, the distribution function (or cumulative distribution function) is defined as the probability \( \alpha \) (0 < \( \alpha \) < 1) that the variate X assumes a value less than or equal to \( x \) and is usually denoted \( F_x(\alpha x) \), or simply \( F(\alpha x) \):

\[
F(\alpha x) = P(X \leq x) \tag{1}
\]

(distinguishing, as customary, between the random variable \( X \) and its specific numerical value \( x \)). The distribution function of any random variable is a nondecreasing (usually increasing) function of \( x \). The range of its values is [0, 1]. (Remember that the cdf is nothing else but a particular probability.)

Besides the cdf, the behavior of a random variable can be described by an "associated" function. The most common of the associated functions (and by far the most often graphed) is the probability density function (pdf), denoted \( f(\alpha x) \). In the case of continuous distributions the pdf is simply the first derivative of the distribution function with respect to the value \( x \) of the corresponding variate \( X \). (In discrete distributions it is sometimes called the "probability mass function," and is obtained by taking the difference of the consecutive values of the distribution function.) As visible from its relationship to the distribution function, the pdf, represented graphically as a curve, possesses two main properties: (1) it is nonnegative for all values of \( x \), \( f(x) > 0 \) (because the cdf is a nondecreasing function of \( x \)); (2) the total area under the curve is 1:

\[
\int_{-\infty}^{\infty} f(x)dx = 1. \tag{2}
\]

By far the most familiar and most widely used of all (continuous) distributional shapes is the symmetric bell-shaped curve depicting the pdf of the normal (or “Gaussian”) distribution. The normal distribution was popularized in the social sciences by the great Belgian scholar Lambert Adolphe Jacques Quetelet (1796–1874).

Other popular associated functions used in social science are (1) the quantile function, which, inter alia, provides the foundation for distributional measures of inequality, such as Pen’s Parade, and (2) the hazard function, formally defined as the ratio of the pdf to 1 minus the cdf: \( f(x)/(1 – F(x)) \). The denominator, \( 1 – F(x) \), is also known as the “reliability function” and as the “survival function” and denoted by \( S(x) \).

All the associated functions are related to each other. For example, as already noted, among continuous distributions, the probability density function is the first derivative of the distribution function with respect to \( x \). The quantile function, variously denoted \( G(\alpha) \) or \( Q(\alpha) \) or \( F^{-1}(\alpha) \), is the inverse of the distribution function, providing a mapping from the probability \( \alpha \) (0 < \( \alpha \) < 1) to the quantile value \( x \). Recall that the range of the values of a distribution function is (0, 1). If the distribution function rises steadily from 0 to 1 there is a unique number \( x_\alpha \) for each \( \alpha \) on the interval [0, 1] such that

\[
F(x_\alpha) = P(X \leq x_\alpha) = \alpha. \tag{3}
\]

The number \( x_\alpha \) is a number in the set of values of \( X \) and it is the value such that the fraction \( \alpha \) (0 < \( \alpha \) < 1) of the total probability (which is 1) is assigned to the interval \((–\infty, \ x_\alpha)\). This number is the \( \alpha \)th quantile of the distribution function defined above, \( F_x(\alpha x) \). (For a standard normal distribution at probability \( \alpha = .5 \), the value of the quantile function is 0, given that the total probability under the normal curve [which ranges from \(-\infty \) to \( +\infty \)] up to value 0 is .5.) Important relations between the quantile and distribution functions are (Eubank 1988; Evans, Hastings, and Peacock 2000):

\[
F[Q(\alpha)] = \alpha, \text{ for } F \text{ continuous} \tag{4}
\]

\[
Q[F(x)] = x, \text{ for } F \text{ continuous and strictly increasing.}
\]
DISTRIBUTIONAL PARAMETERS
Quantities which appear explicitly in the expression of the
distribution function are called parameters. Distributions
usually have associated with them a number of parame-
ters. Of these, three are regarded as basic—the location,
scale, and shape parameters. The location parameter is a
particular point in the variate’s domain, and the scale and
shape parameters govern the scale and the shape, respec-
tively. Variates differ in the number and kind of basic
parameters. For example, the normal (Gaussian) distribu-
tion has two parameters, a location parameter (the mean)
and a scale parameter (the standard deviation); the Pareto
distribution has a location parameter and a shape param-
eter; and the gamma is a three-parameter distribution
(with location, scale, and shape parameters). The gamma
distribution is sometimes specified as a two-parameter dis-
tribution (possessing scale and shape parameters, with the
location parameter being 0).

MOMENTS, MEAN, AND VARIANCE
Borrowing from physics the idea of the moments of a
function, the mean (or expected value) of a distribution
(also referred to as of a random variable) is defined as the
first moment about the origin (0):

\[ \mu = \int_{-\infty}^{\infty} x f(x) \, dx \]  
(5)

( representing an ideal or a theoretical average and charac-
terizing the central tendency). The variance is defined as
the second moment about the mean:

\[ \sigma^2 = \int_{-\infty}^{\infty} (x - \mu)^2 f(x) \, dx \]  
(6)

( representing dispersion of the random variable around
the expected value). The square root of the variance
is known as the “standard deviation” and is usually
denoted \( \sigma \).

SKEWNESS AND KURTOSIS
Two additional quantities are the coefficient of skewness,
denoted \( \beta_1 \) (the positive square root of \( \beta_1 \) is denoted by
\( \gamma_1 = +\sqrt{\beta_1} \)):

\[ \beta_1 = \int_{-\infty}^{\infty} (x - \mu)^3 f(x) \, dx \]  
\( \sigma^3 \)  
,  
(7)

and the coefficient of kurtosis, denoted \( \beta_2 \):

\[ \beta_2 = \frac{\int_{-\infty}^{\infty} (x - \mu)^4 f(x) \, dx}{\sigma^4} \, . \]  
(8)

The numerators of the coefficients of skewness and
kurtosis are the third and fourth moments about the
mean, respectively, and the denominators are the third
and fourth powers, respectively, of the standard deviation.
The coefficient of skewness measures the relative asymme-
try and the coefficient of kurtosis measures the peakedness
(and humpiness) of the distribution. For the normal distri-
bution, the kurtosis is

\[ \beta_2 = 3. \]  
(9)

Evidently, for any symmetric distribution the skew-
ness equals 0, given that every odd moment is zero in this
case. The coefficient of kurtosis is thus sometimes defined
as the expression in (8) minus 3 (usually denoted by \( \gamma_2 \)),
which may lead to ambiguity. (The Greek word \( \kappa\u03b3\u03a9\sigma\) means “humped”).

CUMULANTS
Cumulants (also known as semi-invariants) are simple
functions of moments having useful theoretical prop-
erties. Unlike the moments, all the cumulants (except the
first) are independent of the origin of calculations so it is
unnecessary to specify the origin of calculations in giving
their values.

GROUPS AND SUBGROUPS,
DISTRIBUTIONS AND
SUBDISTRIBUTIONS
Groups and subgroups are pivotal in social science, and
the distributional operations of censoring and truncation
serve to analyze subgroup structures. Using what is by
now standard terminology (Gibbons 1988, p. 355), let
“censoring” refer to selection of units by their ranks or
percentage (or probability) points; and let “truncation”
refer to selection of units by values of the variate. Thus,
the truncation point is the value \( x \) separating the subdis-
tributions; the censoring point is the percentage point \( \alpha \)
separating the subdistributions. For example, the sub-
groups with incomes less than $30,000 or greater than
$90,000 each form a truncated subdistribution; the top 2
percent and the bottom 5 percent of the population each
form a censored subdistribution.

There is a special link between these two kinds of
subgroup structure and Blau’s (1974) pioneering observa-
tion that much of human behavior can be traced to the
differential operation of quantitative and qualitative char-
acteristics. Quantitative characteristics—both cardinal
characteristics (such as wealth) and ordinal characteristics
Probability Distributions

(such as intelligence and beauty)—generate both truncated and censored subdistribution structures. For example, the subgroups “rich” and “poor” may be generated by reference to an amount of income or by reference to percentages of the population. However, qualitative characteristics—such as race, ethnicity, language, and religion—may be related so tightly to quantitative characteristics that the subgroups corresponding to the categories of the qualitative characteristic are nonoverlapping and thus provide the basis for generating censored subdistribution structures. For example, in caste, slavery, or segmented societies, the subdistribution structure of a quantitative characteristic may be a censored structure in which the percentages pertain to the subsets formed by a qualitative characteristic—such as “slave” and “free” or “immigrant” and “native.”

SOME IMPORTANT DISTRIBUTIONS

The number of probability distributions appearing in the literature is now by a conservative estimate far more than 300, and climbing. The standard compendia highlight the basic forty or fifty distributions, and among these, the most important twenty or so appear in all textbooks and in all languages. Chronologically, the earliest distributions that were scrupulously investigated, starting from the early eighteenth century, were the normal (Gaussian) distribution and, to a lesser extent, the Cauchy distribution. The Pareto distribution was proposed by the Italian-Swiss economist and sociologist Vilfredo Pareto (1848–1923) in the late nineteenth century, and the Weibull is of more recent origin, developed by the Swedish engineer Waloddi Weibull (1887–1979) in the mid-twentieth century. Information about univariate and multivariate discrete distributions and multivariate continuous distributions is now easily available, and these are not discussed here due to space constraints. The 2000 handbook by Evans, Hastings, and Peacock provides a lucid introduction to some forty widely used distributions. A more extensive source is the six-volume compendium by Kotz, Johnson, Balakrishnan, and Kemp under the overall title Distributions in Statistics, 2nd ed., 1995–2002. The Dictionary and Classified Bibliography of Statistical Distributions in Scientific Work, edited by Patil, Boswell, Joshi, Ratnaparkhi, and Roux, 1984, is a handy reference source.

We now present a brief description of twelve selected basic continuous univariate distributions. Table 1 reports their probability density function, mean, and variance (for a more detailed table, see e.g. Tsokos 1972, which also provides graphical display).

Uniform Distribution The uniform is a natural conception that has been in use since before printed records. Its applications include corrections for grouping, life testing, traffic-flow analyses, and round-off errors, and it provides a model for the set of relative ranks in a group or population.

Normal Distribution As indicated above, the normal (also “Gaussian,” “Laplace-Gaussian,” and “Gaussian-Laplace”) is the most important distribution in probability theory and in mathematical as well as applied statistics. The normal’s density is symmetric and bell-shaped. Values for the density, cumulative, and inverse of the standard form are extensively tabulated. The importance of the normal distribution is due to the fact that under general conditions, the sum of many independent variables tends, as the number of variables increases, to the normal. The relevant conditions are provided in the central limit theorem.

Lognormal Distribution The lognormal distribution is defined on the positive support; it is unimodal with a long right tail. Its name refers to the fact that the logarithm of a lognormal variate has a normal distribution. The lognormal is widely used in the biological, physical, and sociobehavioral sciences, including economics, and even in philology. It serves as a model for income, physician’s consulting time, sickness absence, number of persons in a census occupational category, height and weight, automobile insurance claims payments, and size of oil and gas deposits.

Exponential Distribution The exponential (more precisely, the “negative exponential”) has a mode at the origin (x = 0) and a long right tail. It is widely used in studies of lifetimes, life testing, and life characteristics, producing usable approximate solutions to difficult distributional problems. It also provides the model for social status in the case where status arises from one (or several perfectly positively related) personal characteristic(s). Its mirror image, the positive exponential, has a mode at its upper bound and a long left tail. Justice processes generate both negative exponential and positive exponential distributions. Recent extensions by Jasso and Kotz (2007) are geared towards applications in the social sciences (see below).

Weibull Distribution The Weibull is an asymmetric single-peaked distribution defined on the positive support. It is widely used in analyses of reliability problems, the theory of sound, health phenomena, human performance, duration of industrial stoppages, and migratory systems.

Gamma Distribution The gamma is defined on the positive support; it is unimodal and asymmetric and has a

Notes: In the formula for the beta distribution, “B” denotes the beta function, and \( \Gamma(\cdot) \) appearing in formulas for the gamma and Weibull distributions denotes the gamma function.

long right tail. It includes as special cases the exponential, whose mode is at the origin, and the Erlang distribution, whose shape parameter \( c \) is an integer. The gamma is used to represent lifetimes and personal income, as well as daily demand for electrical power and the distribution of single-species abundances at equilibrium. It arises also in the study of social status, where it provides a model of the case where status is generated by two or more independent characteristics, and in the study of justice, where it provides a model of the case where the justice evaluation is generated by two or more independent ordinal characteristics.

Pareto Distribution The Pareto has a mode at its positive origin and a very long right tail. It is used to model personal income, firm size, city size, and occurrence of natural resources. Because the Pareto has a positive infimum, it is ideal for modeling income distributions that have a “safety net.” Recently it has been used in connection with the random walk hypothesis of common stock prices.

Laplace Distribution (Double Exponential) The Laplace is a symmetric distribution with a sharp point at its mode—it arises, inter alia, from the difference between
two identical exponential distributions. It is similar to the normal, but the smooth top of the bell is replaced by a needle peak. It is the “prior distribution” in Bayesian statistical analysis. It is used as a substitute for the normal in robust statistics analysis, and provides a model for demand during lead time for slow-moving items. It also arises in the study of justice, in the case where both actual incomes and personal ideas of just incomes are independently and identically Pareto distributed; the asymmetric Laplace form arises in the case where actual incomes and personal ideas of just incomes are independently and nonidentically Pareto distributed.

**Beta Distribution** The beta is a very flexible family, being a generalization of the uniform distribution. It provides the prior distribution for binomial proportions and serves in models and analyses of hydrologic variables, project planning/control systems (such as PERT), tool wear, construction duration, transmission of HIV virus, traffic flow, and risk analysis for strategic planning. Via its special case, the power-function distribution, it also is used to model the income distribution.

**Logistic Distribution** The logistic is a symmetric unimodal distribution defined on the real line. It is used in analyses of growth (including the growth of human populations), quantal response data, psychological issues, weight gain, and physiochemical phenomena. It also is sometimes used as a substitute for the normal.

**Cauchy Distribution** The Cauchy is a symmetric unimodal distribution defined on the real line. Its density is similar to the normal’s but with thicker tails. It has the interesting (and restrictive in applications) property that moments (including the expected value) are not defined. Advances in computational procedures diminish the effect of the absence of moments, and the Cauchy distribution is nowadays often used (in particular in financial applications) as an alternative to the normal distribution.

**Power-Function Distribution** The power-function, a special case of the beta, is defined on the positive support; it can have a left tail or a right tail, depending on whether its shape parameter is larger or smaller than 1. When the shape parameter is 1, the power-function becomes the uniform distribution. Because the power-function has a supremum, it is appropriate for modeling situations marked by scarcity.

To summarize, the normal, Cauchy, Laplace, and logistic distributions are defined for all real values; the exponential, Weibull, gamma, and lognormal distributions are defined for all positive values; the Pareto distribution is defined for all positive values larger than a specified number; the beta distribution (and the continuous uniform distribution) are defined for an interval of a specified length.

Some of the distributions in the list are rivals for modeling some phenomena. For example, the gamma and lognormal are competitors for modeling size distributions, and the exponential and Weibull are competitors for modeling reliability. Many other distributions are used in social science to model sociobehavioral phenomena, and still more distributions arise from sociobehavioral operations. For example, status processes generate, besides the Erlang, a general Erlang and new variates called *ring-exponential* and *mirror-exponential distributions* (Jasso and Kotz 2007). Further, in addition to the pivotal normal, other distributions used in mathematical and applied statistics include the chi-squared, Student’s *t*, and the *F* distribution (central and noncentral).

Finally, special mention must be made of the equal distribution (sometimes called “degenerate” when defined as discrete, and “Dirac’s delta” when defined as continuous), which provides a model for a perfectly equal distribution and thus serves as a benchmark in analyses of social inequality (Jasso 1980; Jasso and Kotz 2007).

PROBABILITY THEORY

With the identification of Huygens’s 1657 book *Ratiociniis in aleae ludo* as its first text, Ian Hacking characterizes the decade around 1660 as *the* decade of the birth of probability. He chooses to bring the story of its emergence to an end with the year of publication of Jacques Bernoulli’s *Ars Conjectandi* in 1713:

In that year probability came before the public with a brilliant portent of all the things we know about it now: its mathematical profundity, its unbounded practical applications, its squirming duality, and its constant invitation for philosophizing (Hacking 1975, p. 143).

Hacking structures his prehistory, a “prehistory … more important than the history,” around the dual notions of the aleatory versus the epistemic: “the degree of belief warranted by evidence” versus the “tendency displayed by some chance devices to produce stable relative frequencies” (1975, p. 1).

Augustin Cournot (1843) and Francis Edgeworth (1884, 1922), and following them in the second quarter of the twentieth century, John Maynard Keynes and Frank P. Ramsey, distinguished students of economy and society, all had a deep and abiding interest in probability theory, but struggled with the definition of their (instrumental) subject. Edgeworth, in particular, settled in his 1884 paper on the description of probability as “importing partial incomplete belief,” but was unsure about “how far the gradations of belief are a subject of science” (p. 223). Returning to the term, and to the “philosophy of chance” forty years later, he flatly stated that “probability seems not to admit of definition” (Edgeworth 1922, p. 257). Already, his 1911 entry on *probability and expectation* for the *Encyclopedia Britannica* had opened with the following demurral:

As in other mathematical sciences, so in probabilities, or even more so, the philosophical foundations are less clear than the calculations based thereon. On this obscure and controversial topic, absolute uniformity is not to be expected (p. 376).

In his biographical essay on Ramsey, Keynes responded to Ramsey’s (1922, 1926) critique of his “objective theory of probability” with a wary ambivalence:

The calculus of probabilities belongs to formal logic. But the basis of our degrees of belief—or the *a priori* probabilities, as they used to be called—is part of our human outfit, perhaps given us merely by natural selection, analogous to our perceptions and our memories rather than to formal logic. So far I yield to Ramsey—I think he is right. But in attempting to distinguish “rational” degrees of belief from belief in general he was not yet I think quite successful (Keynes 1933, pp. 338–339).

In her discussion of the “subjective theory of probability,” Maria Galavotti alluded to Ramsey’s scepticism concerning a single notion of probability equally applicable “in logic and in physics,” and quoted Bruno de Finetti’s bald antirealist claim that “probability does not exist” (Galavotti 1991, pp. 241, 246). Colin Howson’s (1995) conclusion then that the foundations of probability have not yet entered a “final stable phase” was only fitting.

Whatever the final phase and the precise definition, *equipossibility* and *asymptotics* are identified as foundational in any application of the subject. In his endorsement of the equal-treatment property, and of the “utilitarian who thinks it ‘fair’ to treat as equals those between whom no material difference is discerned, … [to] treat as equals things which are not known to be unequal,” Edgeworth relied on the standard of statistical uniformity to consider John Venn’s claim that “whereas full belief about an event is either verified or disproved by the event, fractional belief can only be verified or disproved by a series of events” (Edgeworth 1884, pp. 234, 225). It is of interest to trace the evolution of this Laplacian idea to the role it plays as a principle of indifference in Keynes’s objective theory, and to the assignment of equal initial degrees of confirmation in Rudolf Carnap’s system of inductive logic based on “*logical probability*”; (see Gillies 2000, chapters 2 and 3; Ayer 1963, chapters 7 and 8; and Ayer 1972, chapter 2). Hacking, too, devotes discussion to “equally possible cases,” before moving on to the “first limit theorem” (Hacking 1975, chapters 14 and 17). In his history of the subject in the nineteenth century, he observes an attitude, especially among the French.

When there are enough events they display regularities. This law passed beyond a mere fact of experience. It was not something to be checked against experience; it was the way things had to be. The law of large numbers became a metaphysical truth (Hacking 1990, p. 104).
By the middle of the twentieth century, however, the logical and mathematical presuppositions of such a law were well-understood (see Ayer 1972, section 2.D).

It is now conventional to see Andrei Kolmogorov (1933) as having laid the mathematical foundation of the subject in the theory of measure, and in having brought probability into the mathematical mainstream by providing a rigorous framework for the study of an infinite sequence of coin tosses, and even for an uncountably indexed set of trials. Authoritative texts abound for the mathematics of probability, and the tables of contents in Jeffrey Rosenthal’s *A First Look at Rigorous Probability Theory* (2000) or in A. V. Skorokhod’s *Basic Principles and Applications of Probability Theory* (2004), for example, bring out what is now considered to be the standard subject matter. What is important is that rather than attempting probability on the same rigorous basis as the rest of mathematics, after Kolomogorov, the question turns to the insights that probability can give rather than take from the rest of mathematics: from analysis, dynamical systems, optimization, and even number theory and geometry (see Lasota and Mackey 1994; de Melo and van Strein 1993; Steele 1997; and Dajani and Kraaikamp 2002 and their references). The subject has attained a maturity that it can be studied solely through counterexamples, as in Jordan Stoyanov (1987), but as Joseph Doob (1994a) documents, this mathematical coming-of-age has resulted in some tension between probabilists and measure-theorists. Indeed the issue—a mini-issue really—reduces to the essential difference between a measure and a probability, a difference encapsulated in the concept of independence and in a bounded rather than an unbounded measure: For the former, Mark Kac’s (1964, 1985) elegant emphasis is unparalleled, and for the latter, one can hardly do better than begin with a comparison of Walter Rudin (1987) and Doob (1994b).

A subsidiary question then arises as to the evolution and the autonomy of the subject of *statistics* as distinct from that of *probability*. If the notion of independence is a synecdoche for one, is the notion of *sufficiency* that for the other? If Hacking (1975) is devoted to one, is Hacking (1990) devoted to the other? It is interesting that Ramsey, de Finetti, and Leonard Savage do not make it to the index of Hacking’s investigation of “statistical fatalism,” and how “an avalanche of numbers turned rational moral science into empirical moral science” (1990, pp. x, viii). However, if the distinction between the theories of probability and measure is a mini-issue, the distinction between probability and statistics is almost surely a nonissue, and it would be a naive anthropology indeed that uses professional societies and journals to refute the fact of one community finding its true identity in the other (see Khan 1993 in this direction). In any case, current conventions see Savage (1954, 1962) as consolidating the earlier insights into a strongly contending, if not dominant, framework for statistical decision theory, one in which utility and (finitely additive as opposed to countably additive) probability are intertwined (see Hacking 1965, chapter 13 for evaluation and possible synthesis).

Savage (1954) is also seen as bringing to culmination the original ideas of Ramsey and de Finetti and providing a founding text for individual decision making. His text thus fulfills Edgeworth’s promise of a “mixed science of probability and utility: of what Laplace (1814) calls espérance, the product of probability and utility; that quantity which to maximize is the main problem of the Art of Measurement—of the art proper” (Edgeworth 1884, p. 235). The modern twist lies in the use, nothing if not dramatic, of the theory of expected utility to depart from the notion of expectation as Laplace defined it, and to construct a theory of nonexpected utility. After an identification of Kreps (1988), Karni and Schmeidler (1991) and Machina and Schmeidler (1992) as the relevant texts, I move on.

With the wholesale importation of the idea of a continuum of agents into more applied areas of economics—macroeconomics certainly, but also the economics of labor and industry, albeit in a framework of identical agents buffeted by independent exogenous shocks—a law of large numbers for a continuum of random variables became an instrumental necessity. The models were geared to exploit the plausible intuition that aggregation removed idiosyncratic uncertainty, and it was difficult to see how the averaging operation of Laplace could not cancel out errors without a tilt or a dependence to them, not only asymptotically but also for a suitably idealized limit. In other words, there was a demand for a framework that was hospitable to the averaging of an independent continuum, and could thereby execute what the Lebesgue probability measure could not, and cannot, do (on this, see Doob 1994a; Khan and Sun 1999; and Sun 2006). In a landmark paper, Peter Loeb (1975) offered such a framework, and Yeneng Sun exploited it to deliver not only a law of large numbers, but also a variety of novel probabilistic patterns and dualities concerning independence and exchangeability (see Sun 1998ab). R. J. Aumann’s limitation on the diversity of agent characteristics through the assumption of a finite number of commodities is now translated into a possibly analogous limitation that requires the order of averaging over names and states of nature not to matter, a limitation that yokes Fubini to an event space richer than the one conventionally constructed for products (see Hammond and Sun 2003a, 2003b, 2006a, 2006b). Thus, in its needs and demands for a limit law of great numbers, probability theory was led to supply new adjectives for a probability measure, and thereby surely to go beyond the original Kolmogorov
axioms (in addition to Fajardo’s 1999 overview, see Khan and Sun 2002 and Sun 2006).

Stochastic dynamics, and a surge of interest in functional analysis, had already led probability theory to a study of function-valued and vector-valued random variables, as in Joseph Diestel and Jerry Uhl (1977); after Aumann’s formalization of Edgeworth’s conjecture (see Anderson 1991 for details and references), economic theory led it to a study of set-valued random variables. Laplace’s espérance was correspondingly generalized to sets, as was the induced law of a random variable and the law of large numbers; once random sets are made tractable, it is a small step to the consideration of random preferences, random economies, set-valued martingales, and a variety of other set-valued notions. (In addition to Khan and Sun 2002, see Sun 1999, Majumdar and Rotar 2000, and Bhattacharya and Majumdar 2004.)

We conclude this entry by pointing out that its narrower compass has forced a neglect of the economics of information and the affiliated fields of game theory and finance, let alone the manifold applications to sociology, behavioral psychology, quantum mechanics, and evidence-based bio-medical sciences. But even a briefly adequate view of these other applications surely requires another entry.

Pro-Choice/Pro-Life

The abortion debate in the United States connects to wide-ranging cultural arguments about civil liberties and gender. Legal abortion raises questions concerning the role of women in society, the place of motherhood in social status of the fetus, the separation of church and state, and the legal understanding of privacy. Diverse views on these issues have come to be polarized into absolutist positions named pro-choice (supporting legal elective abortion) and pro-life (opposing legal abortion), politicized terms that do little to characterize the complex experiences of women who face inopportune or otherwise compromised pregnancies.

In the nineteenth century, American women of all social classes could legally procure an abortion, which often entailed using herbal abortifacients. However, as “regular” physicians distinguished themselves from midwives and homeopaths, many lobbied state legislatures to criminalize induced abortion. Shortly after its formation in 1847, the American Medical Association (AMA)
declared human life to begin at conception and not, as midwives and lay women held, at “quickening,” midway through gestation when a woman first feels fetal movement in the womb. In taking an anti-abortion stance, physicians professionalized and also moralized their practice through association with saving lives. By the end of the century, abortion was defined as a medical issue and was criminalized at the state level throughout the United States.

Following legislation in several states relaxing abortion restrictions, the U.S. Supreme Court’s 1973 ruling in Roe v. Wade decriminalized elective abortion in the first trimester of pregnancy, allowing abortion in the second trimester given cause that “reasonably relates to the preservation and protection of maternal health,” and in the third “when it is necessary to preserve the life or health of the mother.” In Roe the court interpreted women’s right to terminate pregnancies and physicians’ right to perform abortions as within constitutional rights to privacy; abortion in the United States is thus framed as a “negative” right to act without government interference, rather than an “affirmative” right guaranteed by the state. It is an historic irony that abortion was medicalized in order to restrict its practice, only to be legalized a century later based on its status as medical procedure, a private matter between patient and doctor.

Supporters of Roe argue that legal abortion is necessary to protect women from unsafe pregnancies and nonmedical abortions. For feminists, women’s “right to choose” abortion in the first trimester symbolizes liberation from patriarchal control over women’s sexual and reproductive lives. It also reinforces a more expansive view of adult womanhood than one rooted in a biological capacity to reproduce. For the 1970s feminist movement, the “right to choose” abortion became synonymous with a woman’s right to choose whether, when, and how often to become a mother.

The American pro-life movement was galvanized by the Roe decision. Grassroots organizing built up a single-issue voting block of Catholics, Evangelical Protestants, and political conservatives. Pro-lifers argue that abortion is a sin and therefore criminal. Many also condemn legal abortion for eroding traditional gender roles and what is taken to be women’s special moral standing based on the capacity to bear children. Pro-life activists redefined the question of “life” in the American abortion controversy as a matter of fetal, rather than maternal, right to life. Ultrasound images of free-floating fetuses are used in propagandistic displays to portray fetal life not only as viable but autonomous, suggestive of personhood—a requisite for having rights. Pro-life campaigns project images of intact, well-developed fetuses despite the fact that 90 percent of abortions in the United States occur during the first trimester, while late term abortions are generally performed only in cases of fetal abnormality. Radical pro-lifers view abortion as a holocaust, a symbol of America’s moral degeneracy. During the late 1980s and 1990s, several abortion providers were murdered by extremists who championed a vision of a Christian nation currently in millenarian “end times,” during which God’s law prevails over human law.

Although pro-choice rhetoric is consistent with American values of self-determination, “choice” may be a limited symbol for reproductive rights; many women experience abortion not as desirable, but as an unfortunate necessity following failed contraception, forced intercourse, or a diagnosis of fetal abnormality. In the 1990s, reproductive rights groups ran into conflict with disability rights activists over the possible eugenic use of elective abortion to limit the range of acceptable human life following prenatal screening, such as for Down’s syndrome. Further, women’s ability to “choose” an abortion in the United States remains subject to federal and state-level legislative restrictions. The 1976 Hyde Amendment restricts government-funded elective abortions (through Medicaid). In 2000, 87 percent of U.S. counties lacked abortion providers.

Following the George W. Bush administration’s 2001 signing into effect of the Mexico City Policy (called the “Global Gag Rule” by reproductive rights advocates), developing countries have felt the effects of American abortion controversies. This policy, cutting off U.S. international aid money to organizations directly or indirectly engaged in abortion-related services, including referral, has also hampered the promotion of contraceptives and HIV-awareness. Illegal abortions continue to be a significant cause of morbidity and mortality among women of reproductive age throughout the nonindustrialized world.

Pro-choice and pro-life are not universally meaningful terms. Worldwide, the legal status and availability of abortion is often determined by government interest in population control, rather than religious or moral concern for life and family. The People’s Republic of China has implemented its one-child policy in part through mandatory abortions; Nicolae Ceaușescu’s regime in Romania, on the other hand, attempted to accelerate population growth by banning abortion and contraception. Under state socialism, reproduction has been considered a form of production subject to government regulation. The Soviet Union provided workers with medical abortion as routine birth control; in impoverished 1990s Russia abortions outnumbered live births two-to-one.

Japan legalized abortion in 1948 when families and the government shared interests in reducing family size. Women in Japan, as in southern Europe, turned to abortion during World War II to cope with wartime poverty.
Initially used by mothers to limit family size but now practiced by women of all ages, abortion in countries like Japan, Greece, and Russia is not regarded as posing a symbolic threat to motherhood. In these countries, economic considerations are said to trump religious belief in guiding decisions to terminate pregnancies. Historic memory of the war and political expectations of the European Union help explain why Italians support legal elective abortion (available since 1978), even as abortion remains highly restricted in Roman Catholic Latin America.

Where abortion is medicalized as routine birth control, a backup to nonmedical contraceptive methods, it is medical contraception rather than abortion that symbolizes women’s liberation. In countries with high abortion rates, family planning workers, frequently trained in the United States or Britain, work to dissuade women from relying on abortion to control births, often by emphasizing potential physical, psychological, and even moral hazards of the procedure. In countries with declining population growth rates, as in Southern Europe, “pro-life” campaign materials imported from the United States are combined with nationalist pro-natal rhetoric.

When influenced by patriarchal, religious, and nationalistic beliefs, legalization can restrict women’s access to abortion. Turkey’s 1983 Population Planning Law allows elective abortion through ten weeks of pregnancy, but a married woman’s husband must consent. Germany, cognizant of the Nazi history of eugenic applications of abortion, requires counseling and a three-day waiting period before granting medically approved abortion.

**PRODUCER SURPLUS**

Market transactions typically increase the well-being of the participants. Consumers, sellers, and input providers may all enjoy a surplus from production and exchange. Producer surplus (introduced by English economist Alfred Marshall [1842–1924]) is the benefit on the production side from voluntarily participating in market transactions. The concepts of consumer surplus and producer surplus are widely used for evaluating policy changes: cost-benefit analysis recognizes that benefits accrue as surplus and so are not always measured in market transactions. Producer surplus consists of gross profits accruing to firms and economic rents accruing to input owners (in special cases, it consists only of one or the other). It is often depicted as the area to the left of the supply curve and below the horizontal line representing price.

A firm’s supply curve is determined by its cost. Two cases are commonly considered. In the first, the quantity supplied increases continuously from zero as the price rises (corresponding to increasing average avoidable costs). Then, the firm’s supply curve is its marginal cost curve. Any point on it characterizes a price and output whose product is the firm’s revenue. The area below the curve is the avoidable cost at that quantity, and hence the area to its left and below the price is this producer’s surplus. The second case covers the standard U-shaped average cost curve. For prices below a threshold level (the minimum average avoidable cost) the firm produces nothing, but at or above this threshold the firm is willing to supply a strictly positive output. Then, the firm’s supply curve is its marginal cost curve above average avoidable cost. The area to the left of the supply curve and below the price is this producer’s surplus. To see this, note that this surplus is zero at the threshold price since the firm is indifferent between producing and not producing. If price increases, the quantity supplied rises and the revenue rectangle expands. The area below the supply curve represents the increase in costs, so the difference is this producer’s surplus. In either case, a firm’s profit equals its producer surplus minus sunk (unavoidable) costs.

If all inputs are supplied to the industry perfectly elastically, input prices are constant. In the long run, the market supply curve is perfectly elastic, reflecting zero profit and zero producer surplus. If the number of firms is fixed (as in the short run), the market supply is the horizontal sum of individual supplies, and producer surplus is the sum of the individual firms’ producer surpluses. All producer surplus accrues to firms since inputs earn no rents.

Now suppose instead that at least one input supply curve slopes upward. This gives rise to an upward-sloping market supply curve because increased industry output bids up the prices of those inputs with upward-sloping supply curves. In the long run, free entry ensures zero profits, and the supply-side benefits from the market accrue only to the owners of inputs whose prices are bid up. The area below the price and left of the supply curve measures the economic rents received by input owners.
With a fixed number of firms, the market supply curve is more inelastic than the horizontal sum of the individual firms' supply curves: firms take input prices as given, but these are bid up as industry output expands. Then, the area between the market supply curve and the horizontal sum represents the rents accruing to input owners.

PRODUCTION
In political economy the term production refers not merely to technical processes but also to the motives and the way human actions are organized to bring the output to existence. Consequently, production is a social process, and a theory of production can be linked to a theory of social development and change. One of the characteristics of production is that it takes time. The Austrian capital theory, and specifically the work of Eugen von Böhm-Bawerk (1889), emphasized the time character of production stemming from the division of labor. Karl Marx emphasized the so-called “realization” problem in his critique of the Say's Law. John Maynard Keynes extended this problem to the role of uncertainty and expectations in monetary production economy.

The idea that production takes time was common for the Physiocrats, but after Adam Smith (1776) put forward the importance of the division of labor for explaining industrial growth, this concept became central for the argument of roundaboutness of production. Increasing division of labor requires more capital goods, and the production of these lengthens the production process. John Rae (1834) argued that increased division of labor goes together with increased durability of capital and hence longer periods of time required for production. Böhm-Bawerk (1889) conceptualized a “production function” in which he made the level of output obtained per unit of capital a function of the degree of roundaboutness of the production method. He argued that more roundabout methods of production are more capital intensive and therefore more productive. Maxine Berg (1980) connected the shift from concern with the division of labor to fixed capital formation to the social conflict in the early 1830s, which was prompted by technological development and by the so-called “machinery question”—the consequences of implementing radically new techniques and forces of production at the beginning of the nineteenth century.

SCOPE OF PRODUCTION THEORY
With the emergence of the marginalist approach in economics in the nineteenth century, relative prices were put forward as the driving force for change, and the scope of production theory in this tradition became conflated with a theory of exchange. As a contrast, Marx, Thorstein Veblen, Keynes, and Dudley Dillard, among others, focused on “monetary production,” where money is not merely “the great wheel of circulation,” as Adam Smith characterized it.

Marx viewed the relations of exchange as a manifestation of the relations in production, which determine the social, political, and spiritual aspects of life (Marx 1859, p. 100). Although it appears as if exchange, or circulation of commodities, dominates production in capitalist economies, production is the causal force in classical political economy. This is not to say that there is no interaction between exchange and production. As Smith argued in the Wealth of Nations (1776), the division of labor, or production, is limited by the extent of the market (or expanding possibilities for exchange). The point is that the consequence of reducing production relations to the exchange and circulation of commodities explains away the contradictions and conflicts of capitalist production. Marx in Capital, Volume I, made this argument in his critique of Say's Law (which holds that supply creates its own demand, and there is no possibility of the economy functioning below full employment), and referred to this tradition in economic analysis as “apologetic economy” (p. 114). Not only was production reduced to relations of circulation in this approach, but also circulation was explained as merely the barter of commodities, which is not characteristic for capitalist economies.

In his 1933 article “Monetary Theory of Production” and in the General Theory (1936) Keynes added a distinct
component to the circuit theory of capitalist production—production of money by means of money. That component was liquidity preference. Keynes argued that money, with its special properties (low or zero elasticity of production and substitution) is crucial for understanding the changes and direction of output and employment at the macroeconomic level. Thus, he reaffirmed the importance of Marx’s realization problem for understanding a capitalist system.

Keynes recognized that because the decisions to undertake investment had to be made before the results were known, and because the future returns from capital assets would be uncertain, the confidence of expectations in the occurrence of future events becomes important for the occurrence of current investment. As a measure for this confidence Keynes proposed the concept of “liquidity preference” to replace the traditional quantity theory where the rate of interest is determined by “real” factors such as the productivity of capital and thriftiness. As a measure of investors’ confidence in their expectations for the occurrence of future events, liquidity preference determines the price that will be paid to possess money today.

MONETARY THEORY OF PRODUCTION

In a monetary production economy the “return” from holding money comes from its liquidity premium (Keynes [1936] 1964, p. 227). Each asset has an expected total return (an own-rate of interest) composed of $q - c + l + a$, where $q$ is the expected income from employing the asset in production; $c$ is the carrying cost; $l$ is the liquidity premium; and $a$ is the expected capital gains (appreciation or depreciation). Physical capital will have a return comprised mainly of the yield it is expected to generate from employing it in production. Carrying costs are insignificant for liquid assets, but they would be large for physical capital that depreciates over time. The liquidity premium has two roles: first, protection from future uncertain conditions (expressed through increased liquidity preference); and second, opportunity for profiting from future uncertain conditions (expressed through animal spirits). Expectations about the returns from new investment are compared to those of existing capital, financial assets, and money. The interest rate on money competes with the expected return from employing capital in production—that is, with the marginal efficiency of capital. A situation in which the expected returns of assets are equal, so “that there is nothing to choose in the way of advantage between the alternative” (Keynes [1936] 1964, p. 228), is defined in Keynes’s analysis as equilibrium—a state of rest, not market clearing. In equilibrium the interest rate on money would be equal to the marginal efficiency of capital. But Keynes notes that this does not indicate at what level the equality will be effective. The expected return from holding money as a store of value could be in “equilibrium” (state of rest) with the expected returns from all existing assets at an income below full employment.

Because money is something that cannot be produced, and demand for it cannot be readily choked off, Keynes came to the conclusion that unemployment develops “because people want the moon”—the object of their desire, money, cannot be produced (Keynes [1936] 1964, p. 235). Thus, Keynes’s monetary theory of production explains unemployment not merely through a realization problem (as other economists employing the concept of the circuit do) but through the nature of money and its relation to production and distribution. In the tradition of classical political economy, Keynes’s monetary theory of production emphasized conflict. However, the marginalist schools based on “real-wage” systems demonstrated a harmony of cooperative exchange and equal status of the various revenue shares in production. This is due to the construction of functional relations between quantity consumed and utility on the demand side, and between quantity produced and cost on the supply side, and the resulting symmetry between consumption and production in the marginalist theory (Bharadwaj 1984).

The proposition that capitalists and workers have symmetrical roles in production was put forward by means of conceptualizing their payments as remuneration for their “services” and contribution to production. Profits are viewed as symmetrical to wages as remuneration for the sacrifices of capitalists and as reward for their “waiting,” in the same manner that wages reward labor efforts. Consequently, the distinction between wages and profits is blurred as these are merely returns for homogeneous “factors of production.” The revenue shares are not qualitatively different, as the distinction between the various factors is also obscured. Overall, the shift toward the centrality of individuals’ self-interest and its role in determining relative prices of commodities put forward a conception of an inherently just, value-free mechanism of distribution and production decisions.

MARGINALIST THEORY AND ITS CRITICS

The analytical construct of supply and demand as an explanation of production and distribution was a departure from classical political economy, and it refocused economic theory onto exchange under competition. Increasing returns created problems for the assumption of competition in the neoclassical system, which was pointed out by Piero Sraffa (1926). The possibility for decreasing overhead fixed costs when output increases provides the theoretical possibility for a monopoly, which violates the assumption of competition. The theory of monopolistic
competition emerged as an attempt to solve this problem. The theory of diminishing returns is grounded in the supposed technical fact that there is a decreasing productivity of the successive portions of a constant factor of production. The understanding that if more and more inputs are applied to a given piece of land the average output inevitably diminishes has been extended to other factors of production, as well as to the theory of consumption in the form of diminishing marginal utility. The latter is explained by “human nature” rather than technical conditions. Indeed, Sraffa (1926) argued that the same is also valid for diminishing returns, as the producer is the one who ranks the alternative combinations of resources according to their returns. If decreasing returns are not a technical fact, then the producer’s technical choices would not be ranked independently of distribution.

Sraffa critiqued the marginalist theory of production in *Production of Commodities by Means of Commodities* (1960) on the grounds that diminishing returns to a variable factor presupposes a possibility of substitution, which is problematic when there is heterogeneity of inputs that are also produced. Joan Robinson in “The Production Function and the Theory of Capital” (1953) also pointed out that substitution between capital and labor inputs does not take place within the production process in the way that marginalist theory suggests. Capital inputs are not simply added to or subtracted from other inputs used in production following changes of relative prices. In the marginalist tradition, relative prices then are interpreted as indicative of relative scarcities, instead of being linked to the production process (Roncaglia 1978, p. 92).

A production schema depicts the principal flows of produced goods in the technically required sequence. Such schema has a corresponding quantity model that refers to a precise system of production equations where the level of final demand determines the level of output, intermediate inputs, and labor inputs. The production schema, together with the quantity schema and the pricing model—referring to a precise system of pricing equations—form the price-quantity monetary production model of the economy as a whole (Leontief 1951; Lowe 1976; Pasinetti 1977; Lee 1998).

In the marginalist tradition the profit, often conflated with the interest rate, is presented as the price of a particular commodity—capital, which is subject to the functioning of the supply and demand mechanism. Thus, an increase in the price of capital would bring about an increase in the supply, and a decrease in the demand for this “commodity.” The problem that Sraffa identified and Robinson discussed is that this reasoning presupposes a measure of capital that does not depend on the distribution of income between wages and profits. Sraffa (1960) showed that such a measure cannot exist. Consequently, the linking of variations in output to variations in the quantity of capital and labor utilized in production is undermined. Under these circumstances, profit and wage rates cannot be determined on marginalist principles. Consequently, this critique of capital disputes the harmonious vision of production and distribution characteristic of the neoclassical exchange-based approach, and brings back the issue of conflict within the monetary theory of production.

**BIBLIOGRAPHY**

In economic theory, a production frontier is a mathematical relationship describing the maximum quantity of output that an organization can obtain from a given collection of resources given the technology in use. An equivalent definition specifies the minimum resources an organization requires to produce a given quantity of output, again given the technology in place. A production frontier is thus the economist's distillation of the detailed information contained in the engineer's blueprints that describe what is possible. Organizations operating on the production frontier avoid waste and are technically efficient. Organizations operating beneath the production frontier waste resources and are technically inefficient. The degree of technical inefficiency increases with the distance to the production frontier.

A cost frontier is a dual mathematical relationship that describes the minimum expenditure an organization requires to produce some quantity of output given the prices it pays for the resources it employs in the production process and given the technology in place. Technical efficiency is necessary but not sufficient for operation on the cost frontier. A second requirement is that resources be allocated efficiently in light of the resource prices paid by producers. Organizations achieving both technical and allocative efficiency operate on the cost frontier and are cost efficient. However, if waste in the organization causes actual output to fall short of maximum possible output or if resources are misallocated in light of their respective prices, then actual cost exceeds minimum feasible cost. Organizations failing to fulfill both efficiency conditions operate above the cost frontier and are cost inefficient. The degree of cost inefficiency increases with the distance to the cost frontier.

Over a short period of time the assumption of a given technology underlying a fixed frontier is reasonable. Over a longer period of time existing technology diffuses and new technologies are introduced. Technical progress shifts the production frontier up, increasing the maximum output that can be obtained from a given collection of resources, or reduces resource requirements for a given amount of output. Consequently, technical progress shifts the cost frontier down, reducing the minimum cost that must be incurred to produce a given quantity of output.

Just as it is not possible to know how fast a human can run one hundred meters, the production frontier and the cost frontier of economic theory are unknown. However, it is possible to identify faster runners and slower runners and to observe improvements in best practice through time. It is also possible to identify best-practice organizations and less efficient organizations and to track their performance through time. Thus, theoretical production and cost frontiers are approximated by best-practice production and cost frontiers.

Approximation requires an empirical technique. In 1957 Michael James Farrell used primitive linear programming techniques to construct a best-practice production frontier. However, his contribution remained largely overlooked for twenty years. In 1977 the team of Dennis J. Aigner, C. A. Knox Lovell, and Peter Schmidt and the team of Wim Meeusen and Julien van den Broeck used statistical techniques to develop a best-practice production frontier concept now known as stochastic frontier analysis. A year later the team of Abraham Charnes, William W. Cooper, and Edwardo Rhodes refined Farrell's linear programming techniques to construct an alternative best-practice production frontier concept known as data envelopment analysis. Both approaches to the construction of best-practice production frontiers have been used to provide empirical measures of relative technical efficiency. Both approaches have been extended to the construction of best-practice cost frontiers and to the empirical measurement of relative cost efficiency.

Best-practice production and cost frontiers have been used to test a variety of hypotheses having a direct bearing on public policy. Perhaps the most significant hypothesis is that market structure matters. A highly competitive marketplace rewards organizations operating at or near best practice with growing market share and penalizes inefficient organizations with shrinking market share, often to extinction. A less competitive marketplace can shelter inefficient organizations. A popular example is provided by trade liberalization, which subjects domestic producers to increased foreign competition. A common empirical finding is that trade liberalization brings aggregate performance gains attributable among other factors to improvements in the efficiency of continuing domestic firms, to entry of relatively efficient foreign firms, and to exit of relatively inefficient domestic firms.

A second popular hypothesis is that ownership matters. Private organizations have different incentives and face different constraints than public organizations. When
the two operate in the same marketplace, one group may
operate closer to best practice than the other. Education
and health care are two sectors in which numerous pub-

clic/private performance comparisons have been con-
ducted, with the empirical evidence being mixed.

A third hypothesis asserts that regulation matters. Ill-
designed regulatory frameworks inhibit best practice by
diverting resources away from production toward compli-
ance. Thoughtfully designed regulatory frameworks can
enhance best practice by providing incentives for organi-
izations to operate efficiently and to improve their effi-
ciency through time. One regulatory context in which
theoretical predictions have been quantified by empirical
investigation concerns the impact of alternative forms of
environmental control on organizational performance. In
this context, however, the private cost of reduced effi-
ciency must be balanced against the social benefits of en-
vironmental protection.

The theoretical concept of production and cost fron-
tiers is universally accepted. However, the empirical
implementation of best-practice frontiers and their use in
the policy arena has attracted some criticism. One criti-
cism asserts that the mathematical framework is neces-
sarily incomplete and fails to incorporate the objectives of
and constraints faced by the organization and its stake-
holders. In 1976 George J. Stigler claimed that “waste is
not a useful economic concept. Waste is error within the
framework of modern economic analysis” (p. 216). A sec-
ond criticism asserts that the empirical implementation
fails to control adequately for variation in the operating
environment, thereby confusing variation in operating
efficiency with variation in factors beyond the control of
management. This concern has inhibited the use of best-
practice frontiers in evaluating the relative performance of
educational institutions, health care providers, and regu-
lated utilities.

PRODUCTION
FUNCTION

The principal activity of a firm is to produce a good or
provide a service, that is, to turn inputs into output. To
represent this process, economists use an abstract model of
production. The central concept in this model is the pro-
duction function. A production function is a mathematical
description of the various technical production possibili-
ties faced by a firm. Algebraically, it is written as

\[ q = f(x_1, x_2, \ldots, x_n) \]  

where \( q \) represents the flow of output produced and \( x_1, \ldots, x_n \) are the flows of inputs, each measured in physical
quantities—for example, the number of bushels of corn
produced and the number of tractors and workers utilized.
Often, production functions appear in textbooks written with two inputs as \( q = f(k, l) \), where \( k \) denotes the
amount of capital and \( l \) denotes the amount of labor. To
simplify, we will use this production function in the
remainder of the entry. Equation (1) is assumed to pro-
vide, for any conceivable set of inputs, the engineer’s solu-
tion to the problem of how to best (most efficiently)
combine different quantities of those inputs to get the
output. Therefore, a production function can be under-
stood as a constraint on the activities of producers that is
imposed by the existing technology.

It is important to stress that, as noted above, equation
(1) is essentially an engineering relationship. As such, it
allows for no testing of economic hypotheses. Actual
observed data are the results of economic decisions in
which the production function is but one constraint.
However, the key question from an economic point of view
is how the levels of output and inputs are chosen by
profit-maximizing firms. Thus, economists use production
functions in conjunction with marginal productivity
theory (see below) to provide explanations of factor prices
and the levels of factor utilization. Whereas the engineer-
ing production function captures the maximum level of
output that can be achieved if the given inputs are effi-
ciently employed, the economic production function
reflects the “best-practice” use of the available input and
output combinations.
PROPERTIES OF THE PRODUCTION FUNCTION

The marginal physical product of an input is the additional output that can be produced by employing one more unit of that input while holding all other inputs constant. Algebraically, \( \frac{\partial q}{\partial k} \) is the marginal physical product of capital, and \( \frac{\partial q}{\partial \ell} \) is the marginal physical product of labor.

It is assumed that both marginal products are positive, that is, \( \frac{\partial q}{\partial k} > 0 \) and \( \frac{\partial q}{\partial \ell} > 0 \) (a negative marginal product means that using more of the input in question results in less output being produced). It is also usually assumed that the production process exhibits diminishing marginal productivity. This means that successive additions of one factor while keeping the other one constant yields smaller and smaller increases of output, that is, \( \frac{\partial^2 q}{\partial k^2} < 0 \) and \( \frac{\partial^2 q}{\partial \ell^2} < 0 \).

Factor elasticity (\( \varepsilon \)) is the percentage change in output in response to an infinitesimal percentage change in a factor given that all other factors are held fixed, that is, \( \varepsilon_k = \frac{\partial q}{\partial \ell} \) and \( \varepsilon_\ell = \frac{\partial q}{\partial k} \).

The marginal rate of technical substitution (MRTS) shows the rate at which labor can be substituted for capital while holding output constant at the level \( q_0 \), that is, \( MRTS = \frac{-dk}{dq} \). It can also be shown that the MRTS equals the negative of the ratio of marginal productivities, that is, \( MRTS = \frac{-dk}{dq} = -\frac{\partial q}{\partial k} \cdot \frac{\partial q}{\partial \ell} \). This expression indicates that the gain in output from increasing \( l \) slightly is exactly balanced by the loss of output from suitably decreasing \( k \) (so as to keep output constant at the level \( q_0 \)). It is important to note that for large ratios of \( k \) to \( l \), the MRTS is a large positive number, indicating that a large amount of capital can be given up if one more unit of labor becomes available. On the other hand, when a large amount of labor is already in use, the MRTS is low, indicating that only a small amount of capital can be exchanged for an additional unit of labor if output is to be held constant. This is the so-called property of diminishing MRTS, which states that progressively reducing the amount of one input while maintaining a constant output level will require progressively large increases of the other input. Diminishing MRTS requires both positive and diminishing marginal productivities and \( \frac{\partial q / \partial \ell}{\partial k} > 0 \), that is, that an increase in capital leads to a higher marginal productivity of labor.

If the production function is given by \( q = f(k,l) \) and all inputs are multiplied by the same positive constant \( t > 1 \), the degree of returns to scale can be classified as follows: (1) constant if \( f(tk,tl) = tf(k,l) = tq \); (2) increasing if \( f(tk,tl) > tf(k,l) = tq \); and (3) decreasing if \( f(tk,tl) < tf(k,l) = tq \).

The MRTS is a useful measure of substitutability of one factor for another, given output. However, it depends on the units in which both labor and capital are measured. An alternative measure, independent of the units of measurement, is the elasticity of substitution (\( \sigma \)). It measures the percentage change in the relative amount of the factors employed resulting from a given percentage change in the relative marginal products (that is, the MRTS). Assuming there are only two factors of production: \( \sigma = \frac{dk}{d\ell} \mid MRTS \). Given that \( k/l \) and \( MRTS \) move in the same direction, \( \sigma > 0 \). However, this is not true in the case of a production function with more than two inputs, in which case there are different definitions of the elasticity of substitution (see Chambers 1994, pp. 27–36). A high \( \sigma \) means that the MRTS does not change much relative to \( k/l \). In the extreme \( \sigma = \infty \), the two inputs are said to be perfect substitutes. On the other hand, a low \( \sigma \) means that the MRTS will change by a substantial amount as \( k/l \) varies. For example, if \( \sigma = 0 \), the inputs are used in fixed proportions and substitution is not possible.

MOST COMMON PRODUCTION FUNCTIONS

Fixed proportions (or Leontief): \( q = \min(\alpha_k, \alpha_\ell, l, k) \). \( \alpha_k \alpha_\ell > 0 \). This production function is characterized by \( \sigma = 0 \), as the marginal products are not defined. In this case, capital and labor must be used in fixed proportions. This production function offers a good approximation to many real-world industrial processes.

Cobb-Douglas: \( q = A k^\alpha \ell^\beta \). This is the most ubiquitous form in empirical analyses at the macroeconomic level. The marginal product of capital equals \( \frac{\partial q}{\partial k} = \alpha_k (q / k) > 0 \) (and \( \frac{\partial^2 q}{\partial k^2} = \alpha_k (\alpha_k - 1) (q / k^2) < 0 \)) provided \( 0 < \alpha_k < 1 \); and that of labor equals \( \frac{\partial q}{\partial \ell} = \alpha_\ell (q / \ell) > 0 \) (and \( \frac{\partial^2 q}{\partial \ell^2} = \alpha_\ell (\alpha_\ell - 1) (q / \ell^2) < 0 \)) provided \( 0 < \alpha_\ell < 1 \). This production function can exhibit any degree of returns to scale, as \( A(k)^{\alpha_k} (\ell)^{\alpha_\ell} = A^{\alpha_k + \alpha_\ell} (k^{\alpha_k} \ell^{\alpha_\ell}) = \gamma^{\alpha_k + \alpha_\ell} q \). In this production function, \( \sigma = 1 \), that is, the elasticity of substitution does not vary with the combination of factors used.

CES: \( q = \gamma (\delta k^\rho + (1 - \delta) \ell^\rho)^{1/(\gamma \rho)} \), where \( \gamma > 0 \) is an efficiency parameter; \( 0 \leq \delta \leq 1 \) is a distribution parameter;
Production Function

\( \rho \leq 1 \) is the substitution parameter; and \( \varepsilon \geq 0 \) denotes the degree of returns to scale. For this production function, \( f(tk, tl) = f(q) \) and \( \rho \) is the substitution parameter, which equals \( \rho = \frac{\sigma - 1}{\sigma} \). This implies that the elasticity of substitution is \( \sigma = 1/(1 - \rho) \).

\[
\text{Translog: } \log q = \beta_0 + \beta_1 \log k + \beta_2 \log l + \beta_3 (\log k^2 + \beta_4 (\log k) (\log l)).
\]
Mathematically, this is a second-order expansion, which is easy to implement empirically. In this case, estimates of marginal products and the elasticity of substitution are functions of the coefficients and the input levels. This form is flexible in that it imposes no assumptions on the elasticity of substitution. Other widely used flexible forms include the quadratic and the square root production functions (Beattie and Taylor 1985; Chambers 1994).

DUALITY

A major development since the late 1960s has been the dual formulation of production theory. This approach consists in recovering through the profit or cost functions the properties of the underlying production function. The cost function \( TC(q, w, r) \) represents the minimum cost of producing output for any set of input costs (see Beattie and Taylor 1985, chap. 6, and Chambers 1994). The dual approach is very convenient in applied work because it deals directly with observed economic data generated by markets (that is, factor prices and output). For example, the Cobb-Douglas cost function dual of the production function \( q = Ak^\alpha l^\beta \) is given by the expression \( TC = kw^{\nu}v^{\alpha_1 + \alpha_2} \), where \( k \) is a constant, \( r \) is the user cost of capital, \( w \) is the wage rate, and \( \nu = \alpha_1 + \alpha_2 \) is the degree of returns to scale.

TECHNICAL PROGRESS

Technical progress in economics refers to the impact of the adoption of new techniques on production (or cost). Analytically, the simplest way to represent technical progress is through a shift in the production function over time, that is, \( q = f(k, l, t) \), where \( t \) is an index of the level of technology. In the analysis of time series data (one economic unit observed over time), time is used as a proxy for \( t \). Technical progress is measured by how output changes as time elapses with the input bundle held constant. The rate of technical progress is defined as \( T(k, l, t) = \frac{\partial \ln f(k, l, t)}{\partial t} \). The representation of technical progress this way, though convenient, is very unrealistic, for it assumes that technical progress does not require new inputs and, further, that the production function maintains the same form as time elapses (see Chambers 1994, chap. 6).

PRODUCTION FUNCTIONS IN APPLIED WORK

In this section, first, we provide some useful references for the reader interested in estimating production functions empirically; second, we provide examples of applications in microeconomics; and finally, examples of applications at the macroeconomic level.

Hands On: Estimating Production Functions Given the availability of computers and sophisticated software packages, estimation of production functions (that is, the use of statistical methods applied to real data in order to obtain values of the relevant parameters, such as the factor elasticities, the elasticity of substitution, or the degree of returns to scale) does not present serious problems from the technical and data points of view. Kenneth Wallis (1979, chap. 2) offers a classical and very accessible introduction to the estimation process. Ernst Berndt (1991, chap. 9) also offers a hands-on approach. R. L. Thomas (1993, chap. 11) offers a modern treatment with discussion of recent advances in time-series econometrics, such as unit roots and cointegration analyses. Estimation of engineering production functions requires the availability of data in physical terms for output and inputs. See Sören Wibe (1984) for a survey of estimation of engineering production functions. At aggregate levels (sectors or total economy), there are now many databases that contain series of output and inputs.

As noted above, economists use production functions in conjunction with marginal productivity theory to provide explanations of factor prices and the levels of factors utilization. Observed prices, output, and inputs are generated by a set of simultaneous relationships, and so it is inappropriate to estimate the production function as a single equation treating capital and labor as exogenous variables. In the simplest case, assuming perfect competition in product and factor markets, the prices of output, capital, and labor are exogenous. In the case of the Cobb-Douglas production function, the marginal productivity conditions are given by the equality of the factor prices to the marginal productivities, that is \( \frac{\partial q}{\partial k} = \alpha_0 q/k = r \) and \( \frac{\partial q}{\partial l} = \alpha_0 q/l = w \), where \( r \) denotes the price of capital (that is, the user cost of capital) and \( w \) denotes the price of labor (that is, the wage rate). The firm’s optimal output and input levels result from jointly estimating these two equations together with the production function \( q = Ak^\alpha l^\beta \).

Examples of Applications in Microeconomics Efficient production decisions require that the marginal productivity of an input equals its market price. Therefore, comparing the marginal productivity with input prices permits
the analyst to test whether inputs are allocated efficiently. Pranab Bardhan’s “Size, Productivity, and Returns to Scale” (1973) is a seminal paper in the literature. Bardhan estimated farm production functions to test the efficiency of land and labor allocations in rural areas of developing economies. Likewise, Hanan Jacoby (1993) illustrates how such tests can be refined and the difficulties in estimating marginal labor productivities.

The degree of returns to scale displayed is of great interest to market regulators. Mergers between rival companies reduce costs and potentially enhance welfare if they are in processes that are subject to increasing returns to scale. Similarly, the argument for granting exclusive franchises to operators providing certain public services (most notably public utilities) hinges upon the assumption that the activity displays increasing returns to scale over the relevant range of output (see Train 1991).

Elasticities of substitution are important for understanding how changes in the price of one input impact the demand for others. Ernst Berndt and David Wood (1975), in the aftermath of the first oil shock, showed that capital and energy were complements in U.S. manufacturing. This implies that fiscal incentives to stimulate investment would promote greater energy use.

**Examples of Applications in Macroeconomics** In broad terms, aggregate production functions are estimated empirically in macroeconomic work for the following purposes: (1) to obtain measures of the elasticity of substitution between the factors, and the factor-demand price elasticities; such measures are used for predicting the effects upon the distribution of the national income of changes in technology or factor supplies; (2) to apportion total growth into the accumulation of factors of production and technical change between two periods; (3) to test theories and quantify their predictions; and (4) to assess the likely effects of macroeconomic policies. Likewise, much work in international trade and labor economics uses the production function as one of its main pillars.

However, the most important application of production functions in macroeconomics is in the field of growth theory. Since the 1980s, the field of growth theory has mushroomed with the development of the so-called endogenous growth models (see, for example, Barro and Sala-i-Martin 1995; Aghion and Howitt 1998; and Valdés 1999). These models posit production functions with increasing returns to scale, an elasticity of capital of unity, externalities, or some combination of these. In order to assess the importance of these assumptions, economists have estimated aggregate production functions for entire economies, for the manufacturing sector, or for more narrowly defined industry aggregates with a view to testing if the real world is characterized by such phenomena. Paul Romer (1987), Robert Hall (1990), Ricardo Caballero and Richard Lyons (1992), N. Gregory Mankiw et al. (1992), David Backus et al. (1992), Susanto Basu and John Fernald (1995, 1997), Craig Burnside (1996), and others have attempted to document the empirical importance of the phenomena of increasing returns and externalities hypothesized by the new growth models.

The other important application of production theory in the area of growth is referred to as *growth accounting*. Here the purpose is to decompose overall output growth into the contributions of factor accumulation and technological progress. In this case, the factor elasticities are not estimated econometrically but assumed to be equal to the factor shares (under profit maximization and competitive markets), which can be obtained from the national accounts. In fact, the purpose of growth accounting is to estimate residually the contribution of technical progress (the shift in the production function) to overall growth. In growth rates, the production function $q = f(k, l, h)$ can be written as $q = \varepsilon_k \dot{k} + \varepsilon_l \dot{l} + T$ where $\varepsilon_k$ and $\varepsilon_l$ are the factor elasticities. The only unknown here is $T$, the rate of technical progress, which can be obtained as $T = \dot{q} - \varepsilon_k \dot{k} - \varepsilon_l \dot{l}$.

**THE AGGREGATION PROBLEM**

Macroeconomic work assumes that the economy produces a single homogenous output with “quantities” of homogenous inputs. In most applied work, this assumption is not even discussed, and applied economists use published (aggregate) data from the national accounts, for example. However, at the aggregate level, output and inputs are not physical quantities. The output of a nation (GDP) must be expressed in monetary units. Capital is not measured as a collection of machines, but as the result of a series of investments (thus also expressed in monetary units) added up through the perpetual inventory method and assuming some rate of depreciation. In other words, in aggregate work, economists actually estimate $V = F(J, L)$, and not $q = f(k, h)$, where $V$ is real aggregate value added, $L$ is total employment, and $f$ is the deflated or constant-price value of the stock of capital. When these variables are used as arguments in a production function, they present a serious problem. This is that aggregate production functions cannot be, in general, derived theoretically. If one asks for the conditions under which a series of microproduction functions can be properly aggregated so as to yield an aggregate production function, such conditions are so stringent that it is difficult to believe that actual economies can satisfy them. In other words, for practical purposes, aggregate production functions do not exist (Felipe and Fisher 2003, 2006).

This led a number of economists to ask the following question: If aggregate production functions do not exist,
what do applied economists find when they get aggregate data and estimate a regression? The answer is that all they do is approximate the accounting identity that relates definitionally the value of total output to the sum of the value of total inputs, that is, \( V_t = W_t + \Pi_t = w_t L_t + r J_t \), where \( V_t \) is real value added, \( W_t \) is the total wage bill in real terms, \( \Pi_t \) denotes total profits (operating surplus in the NIPA [National Income and Product Accounts] terminology) also in real terms, \( w_t \) is the average real wage rate, \( L_t \) is employment, \( r \) is the average ex-post real profit rate, and \( J_t \) is the deflated or constant-price value of the stock of capital. The symbol \( \equiv \) indicates that the expression above is an accounting identity. In a series of papers, Jesus Felipe (2001), Felipe and F. Gerard Adams (2005), and Felipe and John S. L. McCombie (2001, 2003) have shown that this identity can be rewritten as \( V_t = F(J_t, L_t) \). This argument explains why aggregate production functions, despite the fact that they do not exist, tend to “work” (that is, the fit is high when estimated econometrically and, at least at times, the factor elasticities approximate the factor shares), and why it deprives most applied work with aggregate production functions of any meaning and significance.

**PRODUCTIVE CLASS**

SEE Physiocracy.

**PRODUCTIVITY**

Productivity is a measure of output relative to input. It can be calculated in a number of different ways, and in a variety of different situations, both over time and within sets of firms, industries, countries, or other organizations.

The two principal measures are labor productivity and total factor productivity (TFP, sometimes loosely called the Solow residual). For the former, it is typical to take the ratio of output to the quantity of labor input, for example, the number of automobiles produced per production worker or the number of automobiles per hour of production worker time. For the latter, it is typical to take the ratio of output to the weighted sum of a broader set of inputs (sometimes labor and capital together; sometimes labor, capital and intermediate inputs, taken together).

While labor productivity is easier to measure, TFP is often preferred as a measure of productivity since TFP growth represents output growth not accounted for by the growth of inputs, whereas labor productivity growth reflects both TFP growth and changes in the capital to labor ratio.

Although a single productivity number is of some interest, it is often better to have time-series productivity data for a particular unit or a cross-section of productivity data for a range of similar units. Furthermore, the definitions of labor productivity and total factor productivity are straightforward, but there are a large number of potential problems of measurement when it comes to defining just what is meant by output and by the various inputs. For example, in the case of the quality of inputs, should labor inputs be adjusted for the skills of workers and, if so, how? There are also a large number of problems in aggregating various outputs and inputs together. For example, in the case of TFP it is usual to weight labor and capital by their shares in value-added, which makes certain assumptions about the nature of the production function.

Empirically, the majority of work on national productivity growth has been conducted for the United States, which has presented a number of interesting features. First, there was a marked slowdown in productivity growth in the 1970s associated with the economic turbulence of that decade (oil shocks,stagflation, and so on) as well as structural changes (the rise of the service sector which historically has had slower productivity growth than manufacturing, as well as being harder to measure). Second, there has been a marked speedup (especially relative to European productivity growth rates) since 1995, associated with the spread of information and communication technologies throughout the U.S. economy, but most particularly in the financial, wholesale, and retail industries.

International comparisons of productivity are particularly difficult because of problems with exchange rates and differences in industrial structure. The United States enjoys a substantial advantage in terms of output per worker over every other major economy in the world—14 percent higher in 2004 than the G7 average. This is driven by a higher ratio of capital per worker, high labor utilization, and high levels of technology. The relative position of the United States is somewhat less advantageous in terms of output per worker hour. According to data from the Organization for Economic Cooperation and Development (OECD), if the United States in 2004 is taken to have a productivity level (output per hour) of 100, the Eurozone has a level of 87, with the United Kingdom at 86, Germany at 91, and France at 103. Substantially larger gaps remain with other OECD members, with Japan at 70, Czech Republic at 45, and Mexico at 29. The excellent performance of France is often seen as a result of high capital intensity and a labor market that tends to favor employment of skilled rather than unskilled workers.

Finally, the level of productivity is an important determinant of the standard of living, which is often measured by the gross domestic product (GDP) per person. However, higher productivity does not necessarily imply a higher standard of living. In addition to productivity per worker hour, GDP per person also depends on hours worked per worker and the employment rate (employment per person) and these latter two factors are affected by national and local labor market institutions. Based on data from the OECD survey of the Euro area, GDP per person in the Euro area was 30 percent lower than that of the United States in 2002, with just over two-thirds of that shortfall due to lower labor resource utilization and the other one-third due to lower labor productivity.

PROFANITY

Most media and social science treatments of profanity fail to grasp the significance of its underlying neurological, psychological, and sociocultural functions. The term *profanity* generally describes forms of offensive or vulgar speech that are scatological, irreligious, or sexual (e.g., shit, hell, and fuck). The *American Heritage Dictionary* (2000) definition refers to “abusive, vulgar, or irreverent language.” The concept of profanity in most cultures also extends to offensive gestures, such as the middle-finger gesture; behaviors, such as pelvic thrusting; and forms of art, for example, sexual content in the motion picture *The Last Temptation of Christ* or modern artwork such as *Piss Christ* by Andres Serrano.

The preceding works of art are offensive because they affront religion, which is in line with the original usage of the term *profanity*. From the fifteenth through the nineteenth century profanity had a more precise meaning, referring specifically to irreligious speech or behavior and not merely vulgarity. Biblical taboos restricted sacrilegious speech, as defined by religious authorities, for example the commandment not to use the Lord’s name in vain.

The word *profane*, according to the *Oxford English Dictionary* (1899), can be traced in writing to 1483. It literally meant outside of the church, secular, not concerned with religion or religious purposes, and by extension not holy, impure or defiled; as a verb it described treating something sacred with abuse, irreverence, or contempt. This definition of profanity is similar to that for *blasphemy*, which refers to an act of insulting or showing contempt or lack of reverence for God. Blasphemy is currently understood as a pointed attack on religion and religious figures, as opposed to merely showing irreverence. For example, Salman Rushdie’s *The Satanic Verses* (1988) was considered by Muslims to be blasphemous toward Islam because of its insulting references to Muhammad.

The concepts of profanity and blasphemy form an integral part of European law regarding obscenity. British obscenity laws, which formed the foundation of American obscenity law, were adapted by the American colonies in the 1600s. They were predicated on the idea that offensive speech has the power to corrupt and deprave people, especially women and children. Early obscenity decisions in both England and the United States dealt with profanity and blasphemy, that is, speech offensive to religion and religious figures. In the late 1800s there was a shift from religion to sexuality as the basis of obscenity. Around the time of the U.S. Civil War (1861–1865) the postal service broadened its censorship of irreligious material to include materials of a sexual nature (e.g., photographs or post cards mailed to soldiers). A historical analysis by Stuart Flexner (1976) indicated that the power of profanity to offend declined throughout the nineteenth century, being supplanted by sexual words and phrases in the United States and other English speaking countries. Since the early 1900s, obscenity cases in the United States have dealt exclusively with sexual materials and their effects on adults and children.

Educators regard the use of profanity as a problem of style more than an affront to religion. In most modern cultures profanity is regarded as substandard speech and inappropriate in formal communication, for example at school. The changing acceptability of profanity in U.S. society is mirrored in motion picture language restrictions. In the early 1900s, U.S. film censorship boards were highly influenced by the church, and religious profanities were explicitly forbidden. The 1939 American classic *Gone with the Wind* made history when Clark Gable uttered one of cinema’s most famous lines, “Frankly, my dear, I don’t give a damn,” resulting in a $5,000 fine. Jay (1992) reported how language in film was heavily censored in the United States prior to the evolution of the rating system used by the film industry since 1968, which permits hundreds of profanities and obscenities in a film for adults, and fewer in films for teenagers and young children. Offensive language is restricted in almost all media around the world (the Internet and satellite radio being exceptions in most countries); censorship occurs in television, radio, newspaper, billboard, magazine, and advertising content. Profanity is heard more frequently in media than obscenity, but that trend could change.

In the United States, the Federal Communications Commission (FCC) has always regulated obscenity on the airwaves, and following the 1978 Supreme Court ruling in *FCC v. Pacifica Foundation*, expanded its scope to include “indecent” speech, defined as patently offensive references to sexual and excretory functions. *Pacifica* was based on a complaint by John Douglas, a member of the Planning Board of Morality in Media, about a radio station's afternoon broadcast of George Carlin's comedy routine “Filthy Words,” which featured seven words not allowed on television. In the early 2000s, conservative political action committees in the United States (e.g., Parents Television Council, Morality in Media) pressured the Federal Communications Commission (FCC) to ban religious profanity from television and radio. Since 2003, the FCC has vacillated on whether “fuck” is universally obscene or not, depending on the context. The FCC originally ruled that “fuck” was not obscene when pop singer Bono uttered the word at the 2003 Golden Globe Awards. The commission reversed itself in 2004, ruling that it was obscene. When ABC broadcast the World War II film *Saving Private Ryan* in 2005, the FCC allowed the offensive speech because soldiers naturally used profanity and obscenity in the heat of battle.
As profanity came to be seen as less offensive than sexual obscenity, profanity became more common in public places, on television, on radio, and in newspapers. Timothy Jay (1992, 2000) published data indicating that profanities are among the most frequently spoken swear words; they are learned in early childhood and persist into old age. People’s feelings about profanity often depend on their view of religion. Religious people are less likely to use profanity than non-religious people, and religious people are more offended by profanity in the media than are non-religious people. Some religious people are more offended by profanity than by obscenity; for example, Jay (2005) documented how religious working-class women will frequently use obscenities at work but are reluctant to use profanities. Restrictive attitudes toward profanity have led to complaints about profanity in popular media. Although religion-based complaints are predicated on the notion that children will be harmed by profanity, there is no social science data to indicate that profanities are psychologically harmful to listeners.

It is normal for people to use profanity, but its use depends critically on the social context. Brain damaged patients may have difficulty suppressing profanity. Jay (2000) has demonstrated both the universality of profane speech and behavior and the culturally determined nature of profanity by observing the behavior of Tourette’s syndrome patients. Tourette’s syndrome (TS) is a motor disorder characterized by uncontrollable movements (e.g., grimacing, head turning, or arm flailing) and vocalizations (e.g., yelling, grunting, or swearing). Uncontrollable obscene gestures and movements (copropraxia) and speech (coprolalia) occur in 25 to 30 percent of Touretters, and tend to feature the most socially inappropriate behaviors in a given culture. What a Tourettter produces during a seizure depends on cultural and developmental context. English-speaking Touretters might utter obscenities such as fuck, cunt, and motherfucker, brandish the middle finger, or act out vulgar behaviors such as simulated masturbation. A young woman with TS in Kuwait is more prone to expose a naked leg, a gesture forbidden in her culture. Japanese and Chinese TS patients are more likely than English speakers to utter insults based on ancestral allusions (e.g., aunt fucker). Touretters in countries where religion is dominant are more likely to use profanities (e.g., holy mother) than Touretters from more secular countries. Coprolalia in the form of sign language also occurs among members of the deaf community with TS.

Originally meant to denote an offense toward religion, the term profanity now refers to a broader range of offensive speech and behavior, which is regarded by many people as too coarse for public use. Context-sensitive social science interpretations of profanity support a less restrictive view of profanity.

PROFESSIONALIZATION

Several attributes set professionals apart from nonprofessionals: (1) establishing formal means of recruiting and training members for the occupation; (2) creating associations to disseminate knowledge in the field, represent and promote the interests of its practitioners, and regulate and standardize its practices; (3) establishing stringent membership requirements and standards in practice; (4) getting official recognition; and (5) developing a code of ethics to make exclusive claims on qualifications, expertise, and jurisdiction. Taken together, these elements are critical in the making of a profession.

Formal education has gatekeeping as well as status-claiming functions. Requiring someone to receive formal training in a field, via university education, is the first step toward securing monopoly control of specialized knowledge. Formalizing the training process serves to invalidate the claims made by those who have obtained such knowledge solely through experience. Implementing this process would potentially limit the number of people acquiring formal education in the field and, in turn, gain control over who might enter the profession. Having everyone undergo similar training would also standardize the socialization process for all practitioners in the field.

Besides requiring formal training at schools, establishing professional organizations contributes to professionalization. Stringent membership criteria underscore the overall strength of a professional organization, which could be a unifying force for its practitioners. If the practitioners could agree on a set of universal standards to clearly define themselves, they could restrict membership to those who can meet the stringent requirements for full memberships and, more important, set the stage for a full closure in the profession (i.e., collective control over entry
Professionalization

into the profession). Thus, nurturing unity and maintaining a strong spirit of professionalism would enhance the professional standing of its practitioners. Conversely, changing or lowering membership requirements reflect practitioners’ loose attachment to the profession and a lack of closure.

The process of securing closure is incomplete without legal backing from the state. Licensure allows practitioners to ward off competition from outsiders. Aside from restricting entry, state laws give all practitioners the exclusive right to perform certain tasks or to provide services in the market. State licensure constitutes the “grand prize” in securing control over one’s work. For example, certification by degree and examinations allows medical doctors and lawyers to eliminate potential competitors from related fields. In these professions, experience cannot be substituted for certification.

Developing and accepting a code of conduct is vital for the development of a profession. A professional society sets clear boundaries of acceptable professional values and conduct for its practitioners. Adopting an ethics code also signifies members’ commitment to the interest of the public (or clients) rather than to a third party. To gain and maintain the public’s confidence in practitioners’ integrity, skills, and performance, practitioners are expected to live up to the code of ethics. Developing professional guidelines can be construed as the final stage of securing jurisdiction control. A set of professional ethics for, by, and of the practitioners preserves their professional standing as well as autonomy. It is a means of maintaining internal control as much as a measure of minimizing external interference.

The code of ethics for professionals first and foremost proclaims members’ commitment to the public and their dedication to the values of the profession. The profession requires members to have a strong sense of dedication and commitment to the profession. The code also spells out the obligations and responsibilities of the practitioners to the profession and to their peers: being loyal, trustworthy, and honest; using discretion and exercising good judgment; and holding one’s and others’ actions to the highest standards.

Being a professional is a tall order. The code of ethics for a profession not only unifies practitioners, it implies that the practitioners themselves have the desire, ability, and obligation to monitor their own professional behavior. The penalties for those who fail to live up to the pledge would be reprimand, suspension, or termination of licensure. This code of conduct is developed to fulfill a sense of professionalism among practitioners. It is also a self-declaration of the profession’s autonomy, high status, commitment, and self-policing.

The career model of professional development postulates that professionalization is sequential in that there is a fixed pattern of development, evolution, and internal differentiation. Each of the elements noted earlier constitutes a chronology of events in professionalization. Social scientists have used the career model to make sense of the developmental process for established fields (e.g., medicine, law, theology) and new occupations (e.g., computer science, engineering).

Practitioners in “new” professions are organized differently from those in “old” professions. For instance, medical doctors have kept jurisdiction control firmly in their hands through formal training and mandatory licensing. They strive for autonomy, status, and recognition in the society, rather than aspiring to be entrepreneurs.

The functional model pays attention to how and to what extent these activities foster professional development. The sequencing of these functions is closely linked to professionalization. Practitioners first call for exclusion, followed by the establishment of jurisdiction, internal controls, and external relations. Professional development is seen as an outcome of different stages of securing control over jurisdiction in a field.

The professional model focuses on the characteristics shared by professions, rather than on the processes of professional development. All professions share several commonalities. A profession is an occupational group with an abstract, theoretical knowledge base, acquired primarily through extensive formal training. A profession is an activity based on formal training and higher learning. Its practitioners are agents of formal knowledge. Professions enjoy the autonomy to establish their own standards of assessment and control. Hence, self-policing members’ behavior and practices becomes an obligation of a profession. Its practitioners see their vocation as a “calling” rather than simply a job. Members of a profession are expected to have a lifetime commitment to their careers and to develop a strong sense of professional identity and dedication to their work.

There are differences among the three models of professional development in their emphasis on sequence of events, functions, or properties. To set themselves apart from nonprofessionals, professionals ought to have ways and means of defining and maintaining their monopoly power. This common theme highlights the ideological and organizational aspects of professionalism. All three models share a common theme that, due to their unique knowledge bases, professions have the desire for authority and freedom, though in varying degrees, to set their own boundaries of expertise, internal and external control, and activities.
Not all professions are truly “free” professions. Medicine, law, and dentistry come close to having all of the characteristics of a profession. Doctors and lawyers have been able to maintain control over their jurisdiction. Dentists also enjoy a high degree of professional autonomy compared to their counterparts in accounting. Entry to medicine, law, and dentistry is regulated by academic and nonacademic requirements. Only licensed doctors, lawyers, and dentists can practice in the United States. These gatekeeping techniques are so effective that even foreign nationals with similar credentials or experience from abroad cannot practice in the United States unless they satisfy the U.S. licensing requirements.

In contrast, there are fewer restrictions to move into other professions. Engineering will never come close to being a truly autonomous profession. It is a semiprofession in that it has a body of specialized knowledge and requires extended training. However, in the absence of mandatory licensing for all entrants, it cannot effectively block anyone without a college degree from becoming an engineer. Engineers do not enjoy legitimate protection from competition in the labor markets. Contemporary engineering can be considered a bureaucratic profession. Due to the organization and nature of engineering work, it is impossible for its practitioners, including the self-employed, to insulate themselves from business and industrial influence. Not only do engineers not have the means to be completely independent from the patrons of their services, they may not have the desire to be independent. Engineers tend to seek power, status, and mobility within an organization. A strong orientation to their profession may be counterproductive to career advancement in bureaucratic institutions.

Experience can substitute for formal education in computer work. Employers can promote an experienced worker without an advanced degree in management to head a division of young, college-educated workers. Degrees in social work are required for some but not all social workers. The military is different from other professions in that extensive training is required for all participants. Compared to their counterparts in civilian employment, workers in this “total institution” do not enjoy a high degree of professional independence. However, one can make the argument that the rites of passage into the military may induce a relatively strong sense of professional commitment. Advanced degrees in one’s field, such as a doctorate, are usually required for teaching in higher education. Yet, a medical degree is not required for teaching in medical schools. None of these professions in the civilian sector has a monopoly of jurisdiction control. The good news is that outsiders enjoy greater access to these professions than to the legal or dental professions. On the other hand, talented individuals may be more attracted to professions with tighter gatekeeping for social status, autonomy, and earnings.

Administrative and managerial positions have been classified as “professional occupations” in the U.S. Census and in scholarly research. Those who perform primarily administrative or managerial tasks may have received formal (e.g., a master’s degree in business administration) and ongoing professional or organizational training. There are professional associations (e.g., the American Management Association) for managers to advance members’ career interests. However, administrators may not possess as much professional autonomy as do doctors or dentists. Like scientists or engineers, managers are semi-professionals.

**PROFESSORIATE**

The professoriate comprises faculty in postsecondary institutions who have specialized expertise in one of the many academic disciplines or professional fields and who teach and to varying degrees engage in research, institutional governance, and service (for example, provide medical care). In the early twenty-first century the professoriate includes approximately 3.5 million professionals teaching more than 80 million students worldwide (Task Force on Higher Education and Society 2000).

The evolution of the academic profession has been inextricably linked to changes in fields of study, colleges and universities, and national systems of higher educa-
The kaleidoscope of organizational structures and operations that characterize postsecondary institutions are associated with an array of faculty employment and career patterns as well as differences in the nature of academic work. The teaching and research of a psychologist differ from a chemist's, and the career path of a professor in a German university only slightly resembles that of a professor in a small American liberal arts college. Hence treating the professoriate as a single professional group is often difficult.

Despite the differences, there are some core features of the profession that can be attributed to the common origins of most contemporary universities in the medieval European universities. Specifically, a history of the professoriate should take into account the nature of academic work, professors' autonomy, and their roles in institutional governance.

HISTORY OF THE ACADEMIC PROFESSION
A fundamental difference in the overall governance of higher education distinguishes the United States from other nations. Whereas in most countries there is a national system of public higher education with government bodies that set policies for all institutions under their jurisdictions, this is not the case in the United States. In the United States control of higher education is decentralized, and responsibility for funding and governance is delegated to individual states. States in turn have given individual universities leeway to establish their own faculty employment practices. Consequently, variations among campuses are greater in the decentralized U.S. higher education "system" than is the case in a centralized one, where conditions of employment are determined by national policies. For a variety of reasons, countries with centralized national systems are looking to the United States as an example of how professorial roles might be restructured. Hence it is instructive to consider the history of the U.S. professoriate in some detail.

The Professoriate in the Decentralized U.S. System The earliest colleges, founded in British colonies, were modeled after Oxford and Cambridge, and their mission was to prepare children of means for public life and further study in medicine, law, or theology. Education was for the privileged class—the elite—and the classical curriculum varied little from that found in the Middle Ages: ethics, metaphysics, and natural philosophy. The language of instruction was Latin.

From the opening of Harvard College in 1636 until the early 1800s, tutors predominated in the professoriate. Recruited from among recent graduates, tutors were considered qualified to teach all subjects. The curriculum was set, and campus governance was the responsibility of a lay board and a strong president.

In the 1720s Harvard made the first “permanent” faculty appointments: endowed professorships in divinity, mathematics, and natural philosophy. Professors differed from tutors in that they usually had some advanced professional training, were appointed to and taught almost exclusively in one subject area, and remained in their positions longer. By 1795 approximately 105 professors were distributed across nineteen colleges. However, the faculty career was not financially viable, so most professors also earned incomes as clergymen, lawyers, and physicians. In the early 1800s the work of Enlightenment scholars, emphasizing scientific reasoning and truth, edged into undergraduate curricula. New areas of academic knowledge with new modes of research emerged, bringing opportunities for postbaccalaureate education outside the traditional professions. The German university, with its ideals of unfettered inquiry and faculty simultaneously engaged in teaching and research, became the model to which the United States aspired, and Americans went abroad for advanced education.

The late 1800s brought specialized colleges for women and blacks and land-grant institutions devoted to utilitarian education. Disciplinary associations (for example, the American Chemical Society) were established, providing avenues for faculty publication that brought national recognition to scholars and their universities. American doctoral education began in earnest. Yale granted the first PhD in 1861, and in 1876 the first exclusively graduate school was founded—Johns Hopkins University.

Further differentiation of postsecondary institutions occurred as the American graduate university began to take shape alongside the liberal arts, specialized, and land-grant institutions. Its core was a four-year undergraduate college organized into disciplinary departments, with graduate and professional programs arrayed around it. These universities exerted profound influences on the definition of academic knowledge and on the professional norms and values of the professoriate. In 1913 faculty in the leading graduate universities called a meeting to set professional standards for university-based scholars, paving the way for the founding of the American Association of University Professors (AAUP) in 1915.

The late 1800s and early 1900s were pivotal years for the academic profession. The earned PhD was becoming a requirement for entry. Growing numbers of individuals moved directly from doctoral study to faculty positions. The ranks of instructor, assistant professor, and professor were forged into a distinguishable career. Individuals were appointed in departments representing specialized disciplinary areas. Structural changes in universities enhanced
professors’ work autonomy and their authority in academic personnel matters. Primary responsibility for academic decisions such as curriculum and faculty hiring migrated to professors.

Between 1921 and 1945 state and federal governments recruited faculty to help solve societal problems, increasing the visibility and stature of the professoriate. The prestige of graduate universities became calibrated in terms of student quality and achievement and faculty prominence and research accomplishments. Between 1920 and 1940 the annual production of doctorates increased from 620 to about 3,300. At the same time new institutions—two-year colleges and normal schools with qualitatively different programs—were created to meet the needs of immigrants and part-time students interested in technical and semiprofessional occupations. Nationally, institutional differentiation and enrollments increased. Student and faculty profiles changed as access to higher education widened and the “massification” of higher education progressed.

Although the professoriate grew in stature and assumed primary responsibility for academic matters, faculty served at the pleasure of institutional governing boards and presidents. Faculty did not enjoy the economic security or due process that characterized other professions, and they chafed at restrictions on their academic freedom. The AAUP, with the American Association of Colleges, crafted professional guidelines to address these problems and in 1940 produced the Statement of Principles on Academic Freedom and Tenure. The statement articulated the concept of continuous tenure, meaning that an individual could not be fired without a judicial hearing, and provided guidelines for awarding tenure. The authors preferred tenure as a means to protect academic freedom and ensure “a sufficient degree of economic security to make the profession attractive to men and women of ability” (American Association of University Professors). Another AAUP report on faculty governance from this period asserted that professors were not employees to be managed by administrators but professionals to be consulted on institutional decisions—in particular faculty appointments and promotions and educational matters.

After World War II, as a result of federal legislation such as the GI Bill, enrollments tripled, as did the need for professors. Established graduate education programs grew, and new ones were created. Government funding for research burgeoned. The confluence of these events in the 1950s further expanded the influence of graduate universities, diffusing the research ethos throughout academe. The specialized scholar came to epitomize the academic professional.

In the 1960s faculty enjoyed ready employment, funding for research, career advancement, and geographic mobility. Faculty autonomy strengthened as departments assumed primary responsibility for academic decisions and faculty personnel matters. The standards for faculty promotion and tenure heightened. Economic conditions worsened in the 1970s, and undergraduate enrollment declined. Professors were criticized for valuing esoteric research, being inattentive to undergraduates, and failing to diversify by hiring and promoting women and minorities. Beginning in the 1980s the nation’s economic policies shifted greater responsibility for funding their education to students and encouraged greater cooperation between postsecondary institutions and business. State and federal governments called for greater fiscal and educational accountability.

Beginning in the 1990s and continuing into the early twenty-first century reduced campus budgets, attributed to lost tax dollars and diminished tuition revenue, and the need for instructional flexibility were reasons given for significant changes in personnel practices. Faculty appointments were changed from tenure track, with its assumption of continuous employment, to term appointments that specify a fixed period at the end of which a person is released or the contract is extended. The proportion of the U.S. professoriate employed full-time dropped from 78 percent to 56 percent between 1970 and 2001, and the majority of full-time appointments in the 1990s were off the tenure track—about 53 percent in 1997 (Finkelstein and Schuster 2001). Unionization of non-tenure-track faculty has increased, providing an alternative to traditional forms of shared governance on some campuses.

The Professoriate in Centralized Higher Education Systems Certain factors have had pervasive and similar effects on the professoriate in both the United States and other countries. For example, new modes of inquiry as well as calls for more utilitarian programs of study have altered postsecondary institutions and the nature of academic work worldwide. However, different national contexts and cultural traditions have led to variations in employment conditions and career structures within the professoriate. For example, in the former Soviet republics, the requirements for different programs of study and rigid workload guidelines are set by the national government and constrain faculty autonomy in their teaching. In western Europe professors participate in and greatly influence decisions about academic matters, but nonprofessors have little to no power. Some nations maintain separate organizational structures for professors’ teaching and research, such as the research institutes and academies of science found in Germany and throughout eastern Europe. Yet Britain has created an institutional ranking system in which placement depends heavily on the research productivity of the university’s faculty. In certain nations—

INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION

519
France, Germany, and Italy, for example—professors are civil servants and enjoy a form of tenure based on their status within the public-service sector. In contrast, the British government removed faculty from the civil service ranks, and now all faculty hold fixed-term appointments. Professors in Latin America must compete periodically with a national pool of applicants for the positions they hold. Some countries—China, for example—are implementing policies that will require faculty to fund parts of their full-time positions with money obtained through research grants.

Such examples highlight variations in the professoriate across centralized higher education systems. Academic work continues to be shaped by changes outside as well as within academe, and it appears that several professional features of the professoriate—autonomy and career stability in particular—are being eroded.

PROFESSIONAL REQUIREMENTS

The configuration of faculty activities and the credentials of professors vary by field, institutional mission, and national context. In the United States, for example, a research university professor with graduate and undergraduate students and a research laboratory distributes her or his time differently than does a community college professor who teaches five or more undergraduate courses. In France the credentials to teach lower division university courses are the same as those required to teach in the elite university preparatory schools.

U.S. colleges set their own personnel policies and practices, but typically, when they seek tenure track faculty, they announce openings in national venues. Search committees made up primarily of faculty screen applicants, interview candidates, and ultimately recommend preferred candidates to administrators. Selection is based on merit criteria, such as academic credentials, publication quality, and peer recommendations. Fixed-term appointments are handled differently, especially if the employment period is brief. In countries with national systems, traditions differ, but typically a government body establishes personnel policies and practices for all postsecondary institutions.

The U.S. tenure track has three ranks: assistant professor, associate professor, and professor. After a probationary period, assistant professors are evaluated and are either promoted to associate professor and awarded tenure or dismissed. Reappointments and promotions of fixed-term faculty are also based on performance evaluations. Faculty may be dismissed from their tenured or non-tenured positions because of misconduct, financial exigencies, or post-tenure reviews that document inadequate performance.

In other countries the sequence of positions held by nonprofessors varies greatly, as do national policies regarding whether a person can earn promotion in the university where he or she is currently employed. In contrast with the United States, where faculty can be promoted through the ranks in a single institution, the careers of academics unfold within national systems. Faculty must often migrate from one institution to another to advance their careers. The Humboldtian university chair system, in which each discipline (department) has one professor—the chair—was copied widely and has significantly influenced faculty careers in many nations. A professor enjoys permanent employment, but nonprofessors are on fixed-term contracts, and to be promoted, they must successfully compete for a position at another university. Nonprofessors must complete a “second doctorate” (the Habilitation) to be eligible for a professorial appointment. While they complete the Habilitation, these nonprofessors hold either paid or unpaid university teaching and research appointments. Unlike in the United States, where junior faculty and professors participate in decision-making with respect to a range of academic issues, in Germany a significant gap in authority exists between these two groups.

SOCIETAL PERCEPTIONS

Throughout the 1950s and 1960s, public views of the academic profession were positive, and occupational prestige was high. However, public perceptions began to change in the 1970s. Criticism of the professoriate appeared regularly in the popular press, students rioted in some countries, and there were general calls for accountability. Faculty productivity, instructional quality, research relevance, and tenure were all questioned in the last thirty years of the twentieth century. The political beliefs of faculty, particularly in the social sciences and humanities, have also drawn criticism. As guaranteed employment and pay in other professions declined, disapproval of U.S. institutional tenure and presumed tenure of professors who are civil servants intensified. However, sociological studies suggest the occupation has remained among the highest in prestige.

CHALLENGES

The academic profession faces multiple challenges. Here are a few:

- One challenge results from government pressures for accountability and structural changes in faculty roles. Proponents of increased efficiency and those who want to change the balance of power among faculty, administrators, and government bodies argue that tenure (both as defined in the United
States and in national civil service careers) is outmoded and advocate fixed-term faculty appointments as an alternative. Critics of such appointments believe they diminish the quality of the professoriate and the conditions of academic work that have made higher education successful: professional autonomy, academic freedom, and economic security. These divergent views of the professorate are a source of tension among government officials, university administrators, and faculty.

- Since the nineteenth century, teaching and learning through simultaneous engagement in scholarship and instruction has been a cornerstone of the strongest higher education systems in the world. Critics of personnel policies that prioritize fixed-term positions with heavy teaching loads challenge what they believe is a failure to recognize the impact on the advancement of knowledge that has resulted in countries that have adopted such practices.

- Yet another challenge for the professoriate is changes in government and foundation research support. Funding for research in some areas is abundant. In others, especially the arts and humanities, monies are scarce. The attractiveness of fields and the availability of future scholars may be affected by this situation.

**PROFILING, RACIAL**

SEE Policing, Biased.

**PROFITABILITY**

At first sight profit appears to be a simple concept that is defined as the residual of revenues from the cost of production; the related concept of profitability is defined as the ratio of profits to some basis, with the most commonly employed basis being invested capital. The simple concept of profitability is of great significance for understanding the motion of the capitalist system because the desire for and promise of profit motivate entrepreneurs to initiate productive activity and because the level of profitability is the measure of the success or failure of an endeavor. Consequently, measuring current and past profitability as well as projecting future profitability is crucial for entrepreneurial decisions with regard to the expansion or contraction of investment in the current activity or alternative activities, the possibility of takeovers, and the like.

**DEFINITIONS OF COSTS AND PROFITS**

In spite of the fact that profitability appears to be easy to define, a closer examination reveals that in reality costs, which are crucial for the determination of profits, are difficult to define in a generally accepted way. The usual textbook discussion of costs refers to the definitions of costs by accountants and economists. Definitions by accountants record only explicit costs, that is, all monetary expenses incurred in the production and sale of goods and services, whereas those by economists include additional costs called the implicit or opportunity cost: the compensation for not exploiting the best alternative opportunity. Clearly, the notion of profits of the economist includes that of the accountant, and this implies that profits in the economist’s sense exist if the revenues from sales exceed both the explicit and the implicit costs. Economic profit
sometimes is referred to as supernormal or excess profit, and the normal profit (rate) is the part of the cost that usually is identified with the interest (rate).

In light of these distinctions, it is clear that there is no single definition of profitability even for accountants because costs and therefore profits depend on various accounting practices and the purposes they serve. For example, accountants usually convey different pictures of a firm's profitability to the government and to the stockholders. Similarly, economists use different measures of profitability, such as profits over invested capital and profits over equity, among a host of others. However, the Cambridge capital controversies show that it is difficult to deal with profitability because it involves the evaluation of capital goods, which requires the prior knowledge of equilibrium prices. Those prices can be estimated only if one knows the average rate of profit of the economy. That estimation, however, requires the evaluation of invested capital, among other things, creating a vicious cycle from which there seems to be no exit.

MEASUREMENTS OF PROFITABILITY

Thus, economists have further difficulties in the estimation of the proper notion of profitability, which usually is identified with the internal rate of return (IRR): the discount rate that equalizes the value of the investment project with the present value of the future stream of expected profits that will result from the lifetime of the investment project. The IRR concept has certain limitations that, among other things, have to do with the idea that only the short-term horizon is relevant for investment decisions. This is why economists make use of the economic rate of return (ERR), which is the IRR over a specific, much shorter period of the firm's life. Even this notion of profitability, however, is hard to measure with actual data, and so economists revert to the accounting rate of profit (ARP): the ratio of the value of a flow of profit in a specific period to the value of the stock of capital.

It is true that in any particular instance the ARP for firms and industries will be different from the respective ERR. More specifically, in 1983 Fisher and McGowan showed that as a result of depreciation methods, the projected cash profiles over time and the growth rate of a firm make ARPs fall short of a good approximation to the ERP. The problem with these experiments is that they were performed with numerical examples, not with actual data. By contrast, in 1990 Duménil and Lévy, using actual data from the U.S. economy over a long period, contended that for all practical purposes and under certain conditions and for certain types of economic problems the ARP can serve as a reliable approximation of the ERR.

In spite of criticisms economists use the notion of the ARP in many applications, such as industrial organization studies; if a particular industry makes an ARP above the economy's average ARP for a considerable period, economists say that this may be evidence of economic (sometimes called excess or even supernormal) profit that accrues to a firm or an industry. This may be due to the exercise of monopoly power or the presence of barriers to entry, which prevent new firms from seizing such profit opportunities. Economic profit is viewed as a departure from the ideal of perfect competition, and the government must take action to correct the situation in its effort to make economic life look more like the perfectly competitive model, in which economic profit in the long run is zero. Furthermore, the ARP has been used, along with other variables, in econometric specifications as a determinant of investment behavior and capital accumulation. The idea is that excess profits attract investment, and therefore capital accumulation accelerates to the point where excess profits are competed away; the opposite is true in the cases of losses.

ARP also has been used in historical studies as an indicator of the expansion or contraction of an economy. In fact, it has been shown that the contraction phase of an economy is associated with a protracted falling ARP that leads to stagnant or even falling total real profits, giving rise to pessimistic expectations and thus discouraging aggregate investment and increasing the rate of unemployment. The opposite is true with a rising rate of profit, which creates an atmosphere of optimism, encouraging investment spending, lowering unemployment, and setting the stage for prosperity.

PROFITS

Any discussion of profits must carefully distinguish between profits at the microeconomic level of the firm
and profits at the macroeconomic or aggregate level, that is, in the economy as a whole. In mainstream economics, the existence of profits at the microeconomic level is not a complicated issue: An individual firm can make profits or losses in the short run based on its sales and the price at which its good or service is sold. In other words, as long as total revenue is greater than total costs, gross profits are realized. In perfect competition, given the nonexistence of barriers to entry, economic profits are necessarily nil in the long run—a condition of equilibrium analysis, where marginal cost must be equal to marginal revenue.

At the macroeconomic level, orthodox or mainstream economists associate the existence of profits to market imperfections: As stated above, profits do not exist in perfect competition. Yet, by allowing for some imperfections, profits will exist in less than perfectly competitive markets, such as in oligopolistic markets and under monopolistic competition, to name a few. At both levels, profits are always maximized by firms.

A second explanation of profits in neoclassical theory sees them not so much as a surplus value where a firm’s revenues are greater than its costs. Instead, we can also see profits as a reward: If an individual has savings, he can choose to consume today or postpone his consumption to a later date and lend his savings to someone who is willing to borrow them. In this sense, the lender is reimbursed his initial loan plus interest, which is his reward for sacrificing consumption today for consumption tomorrow.

For heterodox economists, however, the existence of monetary profits at the macroeconomic (aggregate) level has always been a conundrum. In fact, as we will see, they do not exist—that is, at the macroeconomic level, profits are necessarily nil in theory. This conclusion poses a number of challenges that are tied to the way in which production is financed and the way money is created by bank credit. Yet, profits must exist so that at the macroeconomic level, firms as a whole are able to cover not only their costs of production but also the interest on their bank debt. So where does the extra money come from? To borrow a popular expression from Karl Marx (1818–1883), how does $M$ become $M'$?

PRODUCTION FINANCE AND THE ENDGENEITY OF MONEY

For heterodox economists, firms do not finance production or purchase capital goods with prior savings. Indeed, unlike in neoclassical or mainstream theory, savings only play a passive role in the production process. This is but the first of the reversed causalities within heterodox economics. Rather, since the economy is seen as a logical sequence of irreversible events that operate in historical time within a monetary economy, savings arise from income that logically follows a prior investment. Two questions arise. First, if investment is not financed by savings, how is it financed? Second, will this have any implications for the generation of profits?

Overall, heterodox economists see the economy as a dynamic interactive process between various social groups, such as wage earners, firms, and banks. Such a class-based approach is at the heart of the explanation of macroeconomic profits.

In a monetary economy of production, as advocated by John Maynard Keynes (1883–1946), this circuit of irreversible events begins with the determination of production plans by firms (planned production)—that is, wages are set and production levels are determined, as are other costs of production, such as the rate of interest, exogenously determined by the central bank according to its policy objectives. At this stage, therefore, firms are able to properly determine their financing needs for the production process to begin. In the aggregate, we can argue that firms need to borrow $M$.

As Keynes pointed out, “banks are special,” in the sense that they are entrusted with the role of financing the production process: They “hold the key.” Banks are therefore an important part of not only the production process but also the realization of profits, as we will see below.

Once firms approach a bank for the financing of their production plans, banks will then evaluate the creditworthiness of the potential borrowers. Provided firms have the sufficient collateral to secure a loan, or provided they otherwise meet the strict lending criteria of the banks—such as the firm’s ability to generate profits, the firm’s net worth, the firm’s ability to withstand transitory shocks, and certain key financial ratios, such as cash flows and debt/equity—they will receive the funds to cover their production costs, which may be called the initial finance phase. Of course, some firms will not be able to secure credit, thereby jeopardizing production and output (Graziani 2003).

Once credit has been secured and a loan is made, usually as a line of credit, firms will draw on their line of credit to pay wages and purchase other inputs of production. As they pay wages, bank accounts of wage earners will increase; money is created. In this sense, the creation of money is parallel to the creation of incomes.

Once incomes are created, wage earners will carry out their consumption and saving plans according to their needs. As they consume, money flows back to firms as revenue as they sell their goods and services to consumers. In this sense, firms are able to capture a portion of their initial outlays from the direct consumption by wage earners in the overall economy. Firms will use these funds to extinguish their existing debt toward the bank, which in the process will also destroy money.
Once their consumption plans are carried out, wage earners will assign the remaining component of their wages to savings. We can identify two types of savings: financial savings, which are used to purchase obligations on financial markets, and hoarded savings, which then remain in the wage earners’ bank account, which consists of the demand for money balances.

Although both types of savings may appear similar, they are in fact very different and play very different roles. In the first instance, when households purchase financial obligations, these funds flow back to firms. Firms will then use these funds to reimburse their debt toward the banking system. In this sense, as Keynes once argued, there is no difference between consumption and financial saving, as they both play the same role. Both are, in fact, part of final financing. This is the reflux phase of the circuit of production. It is the phase of the destruction of money.

From the above discussion of the economy as a monetary circuit, two fundamental conclusions about the heterodox approach can be drawn. First, the money supply is endogenous and responds to the needs of production (Lavoie 1992; Moore 1988; Rochon 1999). Credit creates money, which is another reverse causality inherent in the heterodox approach. Money endogeneity suggests therefore that there is no excess money. The money supply always adapts to the requirements of the economy; such is the characteristic of a monetary economy of production.

Unlike neoclassical theory, where the money supply is an exogenous stock imposed by the central bank, heterodox economists consider the flow nature of credit and money as a fundamental characteristic of production economies. In this sense, the banking system is at the heart of the production process and of the endogeneity of money. The existence of money therefore is the result of debt between firms and banks. Heterodox economists therefore argue that the money supply is credit-led and demand-determined.

The second conclusion, however, is even more important. Indeed, if firms borrow $M$, how can they make any profits if, at best, they succeed in capturing only $M$, assuming no savings? Even more importantly, how can firms in the aggregate generate revenues to even pay the interest on their bank loan?

Granted, the above example is a simplified model, but even if we were to complicate the model by adding a government, the open economy, or additional realistic characteristics of a production economy, it would not change the fundamental conclusion that, at best, firms can only succeed in capturing what they injected into circulation at the beginning of the circuit. The question, therefore, is simple: If profits exist at the macroeconomic level, how can we explain the transformation of $M$ into $M'$?

Heterodox economists have proposed a number of possible solutions to this conundrum. For instance, some have suggested that profits can be accounted for, provided we assume several circuits that overlap with each other. In other words, in the real world, production periods are staggered in the sense that firms or sectors do not borrow and reimburse their debt all at the same time. As such, several sources of monetary outlays would exist simultaneously, thereby providing firms with more than $M$ at any one time.

Another possible solution consists in considering the existence of the state or an open economy. Under each of these conditions, there is an additional injection of outlays coming from the state and from other countries. In this sense, when the government undertakes fiscal expenditures, they increase aggregate demand and translate into additional revenues for firms. Yet, the problem with this solution is that while expenditures are revenues for firms, taxes are a drain on the circuit. As such, for this solution to be a viable and general solution, it requires that governments consistently incur fiscal deficits.

In an open economy, of course, countries are increasing their exports, which increase the proceeds of domestic firms, with which they can extinguish their debt toward the banking system and show some profits. This additional influx of revenue would account for the transformation of $M$ into $M'$. Yet, as in the above example, this solution remains a limiting case, and not a general solution: While exports represent an influx of additional revenues, imports are the opposite. In this sense, this solution only applies in situations of net exports (trade surplus).

There is no doubt that all the above suggestions contribute in some way to the existence of macroeconomic profits. Yet, they all consist of ultracircuit explanations, in the sense that they all require that we amend the basic circuit by allowing some external explanation, such as the state, the rest of the world, or additional, overlapping circuits. What is required is a general theory of macroeconomic profits that applies in all circumstances.

For Marxists, since the value of goods reflect the labor hours used in their production (the labor theory of value), profits can be explained because capitalists are able to extract from labor a greater value out of their work or labor power. In other words, capitalists, as owners of the means of capital, are able to exploit workers: Capitalists are thus able to extract “surplus value” from the workers and enjoy profits.

A GENERAL THEORY OF PROFITS

How can we therefore account for profits within a single period of production without relying on external solutions? Recall that until now, this entry has said nothing about the financing of investment. Yet, just like produc-
tion, investment must be financed. Assume therefore that like wages, investment is financed with the use of bank credit. Yet, unlike wages that are financed with short-term credit that needs to be reimbursed at the end of the production circuit, investments are long-term credit: Firms do not reimburse the whole value of investment within the same period, but rather typically reimburse investment over several periods. In that way, while firms in the aggregate borrow to cover wages (and other costs of production) and the purchase of investment goods, they only reimburse a fraction of that total value, which accounts for the existence of profits at the macroeconomic level.

PROGRAMMED RETARDATION

The concept of “programmed retardation” comprises policies, programs, and instructional practices designed to guarantee educational failure for students. Significantly, following the U.S. Supreme Court’s momentous *Brown v. Board of Education* decision of 1954, education strategies originally implemented to deny quality education to many black students began an overall decline of America’s public schools in both urban and suburban areas. This trend has led writers of dramatically different viewpoints to comment on America’s declining educational competitiveness in the world (e.g., Berman 2006; Friedman 2006).

In April 1983, the National Commission on Excellence in Education, which is part of the U.S. Department of Education, issued a report that stated unambiguously that “the educational foundations of our society are presently being eroded by a rising tide of mediocrity that threatens our very future as a Nation and a people.” The report, titled *A Nation at Risk,* likened the devastation of public education to “an act of war.” “We have in effect,” the report warned, “been committing an act of unthinking, unilateral educational disarmament.” Many Americans seemed shocked by the report’s findings, though they were not a new discovery.

The source of the crisis in public education in many of America’s cities can be traced back to the late 1950s and 1960s. The *Brown* decision ended state-sanctioned racial apartheid in America’s public schools; but the reasoning that all black schools were inherently inferior was incorrect. In a deliberate attempt to distort and evade the Court’s decision, many urban school systems outside of the South installed a pupil assignment policy known as “tracking,” which effectively resegregated many schools by channeling the majority of black students into the lowest “track” early in their educational careers.

Interpreting the *Brown* ruling as an opportunity to improve their children’s education, black residents in many cities across America fought the policy of tracking. In 1969 the community activist Jewell Mazique labeled the policy “programmed retardation,” declaring that tracking was more harmful than the conservative practice of racist segregation in the Old South.

Reasoning that poor education would ultimately hurt black and white working-class children in the nation’s capital, community leaders called for neither racial integration nor segregation. Instead, they demanded quality education. Mazique and other Washington, D.C., community activists defined this educational goal unambiguously, calling for: (1) the distribution and mastery of the fundamental tools of learning—namely reading, writing, computational skills, and thinking; (2) academic motivation; and (3) positive character development (Mazique 2000).

As in so many other urban areas, Washington, D.C.’s black community lost the political struggle for quality education. In 1967, the celebrated *Hobson v. Hansen* case terminated the school system’s tracking policy, but the court claimed that racial integration automatically improved the educational performance of black students. Liberal civil rights leaders and educational managerial elites won the day and began to implement various racial integration policies. By the 1970s, many schools system adopted the policy of racial-balance busing, which transported a percentage of black students (and later Latino students) from their neighborhood schools to white schools in order to achieve racial balance. Magnet school programs and other education experiments also were implemented in order to bring about racial integration.
Because integration is not an end in itself but only a means to an end, the contradictions and dilemmas of this approach quickly became apparent. Authentic racial integration, however, could not be realized with policy strategies that focused mainly on the well-being of white students and their schools. Therefore, as many black students were drawn away from their local schools and communities, these schools and other community institutions continued to decline as a result of neglect and economic impoverishment.

Yet educational managers and civil rights elites put forward racial integration as the singular goal of education, demanding that it be imposed on public schools at all costs. However, the implementation of various racial integration policies did not result in educational equality for black students. This was the case because educational professionals and civil rights elites overlooked the issue of quality education. As a result, good classroom teaching declined, the fundamental tools of knowledge were abandoned, and positive character building was perverted. Beginning in the 1970s, many school systems turned away from teaching students important values, such as respect for others and self-restraint, which severely distorted the acculturation and socialization functions of schooling.

Moreover, as white flight, and later middle-class black flight, from cities to suburbs accelerated in the late 1960s and 1970s, America allowed its urban areas and their schools to decay and deteriorate. In the process, school regimes bused African American and Latino children to an expanding system of largely white and affluent suburban schools in order to achieve “racial balance.” This tactic helped to destroy the sense of community in many urban areas, and inner-city life became increasingly characterized by economic impoverishment, political disenfranchisement, and cultural despair. The consequences of this course of events became evident with the collapse of public education in urban areas across the nation. Ironically, school budgets have continued to rise, along with a growing ossification and inefficiency in urban school bureaucracies.

Adding insult to injury, liberal members of the educational managerial elite rationalized the denial of quality education to black students by applying various theories of cultural deprivation. To observers like Mazique, categorizing African-descended Americans as “culturally deprived” or “culturally disadvantaged” has merely compounded and continued the legacy of cultural domination and the denial of black human dignity that began during the Atlantic slave trade. It is a strategy for keeping the oppressed in a condition of oppression.

These unfortunate educational trends and developments characterized urban and less affluent public school systems in the 1960s and 1970s. Since then, however, even many suburban and more affluent public school systems have experienced an educational crisis. They confront a growing rate of complex problems, including functional illiteracy, violence, increased dropout (and “pushout”) rates, discipline problems, drug use, teenage pregnancy, gang activity, and teacher burnout. As a result, generations of young people are being educationally sabotaged in many public schools across America. In his book Retarding America: The Imprisonment of Potential (1993), Michael Brunner demonstrates that programmed retardation, and especially the failure to teach young people to read, results in increasing juvenile crime and incarceration.

In the current stage of American postindustrial development, the collapse of public schooling is frightening. Continued public school experimentation—including privatizing strategies or policies supposedly designed to “leave no child behind”—has not proved successful in big-city school systems. Yet in the emerging society, knowledge and the management of people are supplanting money and manufacturing as the only sources of political and economic power. Resisting the professional-managerial class’ cultural domination and intellectual imperialism requires that people come to view knowledge and its utilization as sources of power. Learning, therefore, needs to be understood as a lifelong project and an indispensable investment for social development. Educational credentials will more and more be the key to a person’s role in society. However, more than the possession of certificates and diplomas will be required to put one’s knowledge into practice. Knowledge-based performance and decision making will be the necessary attributes of the educated person.

To many observers, a generation or more of urban African American and Latino students have been betrayed by the U.S. educational system, and their educational underdevelopment is undercutting their ability to survive and develop in a postindustrial society grown cynically indifferent to social suffering. To overcome a looming educational crisis, America will need to devise and implement a national educational strategy, guided by the principle that in the new age of knowledge, science, and technology, investment in quality educational advancement is the very foundation of national development and competitiveness.

LINEAR PROGRAMMING

Among constrained optimization problems, the linear programming problem is the leading representative. Linear programming (LP) can be described as the problem of maximizing a linear function $F$ over a polyhedron $X$. This means that the objective function has the form $F(x) = c_1x_1 + \ldots + c_nx_n$, where $c_1, \ldots, c_n$ are given constants, and the polyhedron $X$ is the set of solutions of a system of linear inequalities, say:

$$a_{i1}x_1 + \ldots + a_{in}x_n \leq b_i, \ i \in \{1, \ldots, m\}. \tag{1}$$

In many practical applications, the variables $x_j$ are required to satisfy $x_j \geq 0$. Such a nonnegativity constraint is equivalent to $-x_j \leq 0$, a special case of (1).

Economics is the foremost social science field of application for LP (and nonlinear programming as well). The optimal allocation of scarce resources is a typical example. For instance, suppose a firm manufactures $n$ products from $m$ resources. Each unit of product $j$ consumes $a_{ij}$ units of resource $i$, of which there are $b_i$ units available. It is assumed that the consumption of the resources by product $j$ is proportional to the level $x_j$ of the corresponding production activity; it is assumed further that the consumption effects are additive. In that case, the total amount of resource $i$ consumed by the $n$ production levels $x_1, x_2, \ldots, x_n$ is $a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n$, and each of these sums must not exceed the amount available, namely $b_i$. The unknown production levels $x_i$ are naturally nonnegative. Finally, it is assumed that the aim is to maximize the profit resulting from the production and that it is of the form $p_1x_1 + p_2x_2 + \ldots + p_nx_n$. Thus, the optimization problem is:

maximize $p_1x_1 + p_2x_2 + \ldots + p_nx_n$,
subject to $a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n \leq b_i, \ i \in I_1$
$a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n \leq b_i, \ i \in I_2$
$\ldots$
$\ldots$
$a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n \leq b_i, \ i \in I_m$
$x_j \geq 0, \ j = 1, 2, \ldots, n. \tag{2}$

In some instances, it is appropriate to introduce other linear constraints in (2). These could be output requirements $a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n \geq b_i, i \in I_3$, or material balance equations $a_{i1}x_1 + a_{i2}x_2 + \ldots + a_{in}x_n = b_i, i \in I_4$. What results is still a linear programming problem.

Two historically important cost-minimization problems illustrate further applications of linear programming in economics and planning. The first of these is called the diet problem, which calls for a plan whereby a given set of nutritional requirements can be met from a given set of ingredients at minimum cost. In this case, one has nutritional requirements $r_{j1}, r_{j2}, \ldots, r_{jm}$ for vitamins, minerals,
Programming, Linear and Nonlinear

calories, and so on. These requirements are to be met by combining appropriate amounts of \( n \) ingredients \( j = 1, \ldots, n \) having unit costs \( c_j \), respectively. Each unit of ingredient \( j \) contributes \( a_{ij} \) units of nutrient \( i \). The proportionality and additivity of these contributions is assumed. Thereby, the problem can be stated as:

\[
\begin{align*}
\text{minimize} & \quad c_1x_1 + c_2x_2 + \ldots + c_nx_n \\
\text{subject to} & \quad a_{11}x_1 + a_{12}x_2 + \ldots + a_{1n}x_n \leq b_1 \\
& \quad a_{21}x_1 + a_{22}x_2 + \ldots + a_{2n}x_n \leq b_2 \\
& \quad \vdots \\
& \quad a_{m1}x_1 + a_{m2}x_2 + \ldots + a_{mn}x_n \leq b_m \\
& \quad x_j \geq 0, \quad j = 1, 2, \ldots, n
\end{align*}
\]

The formulation can be modified by including constraints such as upper bounds on the amounts of individual ingredients. This model is widely applied in making animal feed.

The second of these applications is called the transportation problem:

\[
\begin{align*}
\text{minimize} & \quad c_{ij}x_{ij} \\
\text{subject to} & \quad x_{i1} + x_{i2} + \ldots + x_{in} = a_i, \quad i = 1, \ldots, m \\
& \quad x_{1j} + x_{2j} + \ldots + x_{nj} = b_j, \quad j = 1, \ldots, n \\
& \quad x_{ij} \geq 0, \quad i = 1, \ldots, m, \quad j = 1, \ldots, n
\end{align*}
\]

which arises in the context of shipping but, in fact, finds use in other areas as well. In this case, a single commodity is to be “shipped” from \( m \) “origins” to \( n \) “destinations.” At origin \( i = 1, \ldots, m \), there is a supply of \( a_i \) units of the commodity. At destination \( j = 1, \ldots, n \), there is a demand for \( d_j \) units of the commodity. To meet the demands from the supplies it is necessary that \( a_1 + \ldots + a_m \geq d_1 + \ldots + d_n \). The cost of shipping a unit of the commodity from \( i \) to \( j \) is denoted \( c_{ij} \). The cost of shipping \( x_{ij} \) units of the commodity from origin \( i \) to destination \( j \) will be \( c_{ij}x_{ij} \). The total cost is \( c_{ij}x_{ij} + \ldots + c_{mj}x_{mj} \). The assignment problem is a special case of the transportation problem in which \( m = n \) and \( a_i = d_j = 1 \) for all \( i \) and \( j \). Feasibility considerations then force the “\( \leq \)” inequalities to hold as equations. The assignment problem arises in both minimization and maximization situations.

In addition to the aforementioned applications, one finds the computation of optimal mixed strategies in finite, two-person, zero-sum (matrix) games, problems of optimal blending, electric power dispatch, manpower planning, investment planning, and many more. Such topics are covered in George B. Dantzig’s Linear Programming and Extensions (1963).

Standard Form For computational purposes, the constraints of a linear program are usually expressed as a system of linear equations in nonnegative variables. This is called standard form. Any legitimate linear program can easily be brought to standard form. Thus \( a_{11}x_1 + \ldots + a_{1n}x_n \leq b_1 \) becomes \( a_{11}x_1 + \ldots + a_{1n}x_n + s_1 = b_1 \), with \( s_j \geq 0 \), and \( a_{ij}x_1 + \ldots + a_{jn}x_n \geq b_j \) becomes \( a_{ij}x_1 + \ldots + a_{jn}x_n - s_j = b_j \) with \( s_j \geq 0 \). Any variable \( x_j \) that is not sign-restricted can be replaced by the difference of two nonnegative variables: \( x_j = x'_j - x''_j \). A variable \( x_j \) constrained to be nonpositive can be replaced by \( x'_j = -x''_j \).

Duality To every linear programming problem there corresponds a dual problem constructed from the same data used in a different way. The dual problem is again a linear program whose form depends on that of the given problem, which in this relationship is called the primal problem. Thus, if the primal problem is (2), the dual problem is:

\[
\begin{align*}
\text{minimize} & \quad b_1y_1 + b_2y_2 + \ldots + b_my_m \\
\text{subject to} & \quad a_{11}y_1 + a_{12}y_2 + \ldots + a_{1n}y_n \geq p_1 \\
& \quad a_{21}y_1 + a_{22}y_2 + \ldots + a_{2n}y_n \geq p_2 \\
& \quad \vdots \quad \vdots \\
& \quad a_{m1}y_1 + a_{m2}y_2 + \ldots + a_{mn}y_n \geq p_m \\
& \quad y_i \geq 0, \quad i = 1, 2, \ldots, m
\end{align*}
\]

The dual of a linear program in standard form is like (3) except for the fact that its variables \( y_i \) are free (not sign-restricted).

These (and other) pairs of primal and dual linear programs are intimately linked in the following way.

Duality Theorem of Linear Programming Let \( X \) and \( Y \) denote the feasible regions of (2) and (3), respectively. Then

\[
\begin{align*}
p_xx_1 + \ldots + p_xx_n & \leq b_1y_1 + \ldots + b_my_m
\end{align*}
\]

for any \( x \in X \) and any \( y \in Y \). If equality holds in (4), then \( x \) and \( y \) are optimal solutions of their respective programs. Moreover, the primal problem has an optimal solution \( \hat{x} \) if and only if the dual problem has an optimal solution \( \hat{y} \) when this is the case, equality holds in (4). If the feasible regions \( X \) and \( Y \) are both nonempty, then both problems have optimal solutions. If only one of the two problems is feasible, then the objective function of that problem is unbounded in the direction of extremization.

Simplex Method The general formulation of the linear programming problem and the simplex method for its solution were advanced by the American mathematician George B. Dantzig (1914–2005) in 1947. This method
continues to be the main algorithm for solving problems of this class.

The simplex method works with linear programs in standard form and takes advantage of the fact that in order to find an optimal solution, it suffices to confine attention to the vertices of the polyhedral feasible region, \( X \). Starting from a known vertex of \( X \), the method generates a path along the edges of \( X \) as it moves from one vertex to an adjacent vertex. As long as “cycling” does not occur, the process is guaranteed to terminate after visiting finitely many vertices. When the algorithm finds an optimal solution of the primal problem, it reveals an optimal solution of the dual problem as well. However, it may happen that a vertex of \( X \) is not known in advance and will have to be found. Techniques are available for finding a vertex of \( X \) (if one exists) and for preventing cycling.

**Sensitivity Analysis** The optimal value of the objective function of an LP, say (2), depends on the input-output coefficients \( a_{ij} \), the right-hand side constants \( b_i \), and the objective function coefficients \( p_j \). The study of how changes in these parameters affect the optimal value is called sensitivity analysis or postoptimality analysis. The most frequently used fact emerging from this kind of analysis is that (in the nondegenerate case) the rate of change of the optimal value \( z \) with respect to a change in the \( i \)th right-hand side parameter \( b_i \) equals the dual variable \( y_i \) corresponding to the \( i \)th constraint; in symbols 
\[
\delta z = \delta b_i y_i.
\]

**Large-scale Linear Programming** Many practical applications engender very large-scale models, often running to tens or hundreds of thousands of equations and a million or more variables. Solving large-scale problems requires powerful computers and specialized algorithms that often exploit the structure of the coefficient matrix corresponding to the constraints. The decomposition principle of Dantzig and Philip Wolfe (1960) is of this type. It is intended for problems with block-angular structure in which there are many organizational units whose corresponding variables appear in a relatively small number of coupling constraints that represent the central administration and otherwise only in constraints that pertain to that unit.

**NONLINEAR PROGRAMMING**

An optimization model with an objective function or at least one constraint function that is not linear is called a nonlinear programming problem (NLP).

Nonlinearity can arise in many ways, thereby yielding diverse types of NLPs. The oldest and easiest to comprehend are quadratic programming problems, wherein the constraints are just like those of an LP but the objective function is quadratic (rather than linear). The first to identify (and name) this problem class was the economist Robert Dorfman (1916–2002) in his monograph *Application of Linear Programming to the Theory of the Firm* (1951). In analyzing production scheduling for monopolized products, the assumption of constant marginal production costs may not hold. As the monopolist’s production increases, it may begin to saturate the market, thereby lowering the price at which products can be sold. Alternatively, the monopolist can restrict production in order to uphold the price of the product. Dorfman’s model covers those cases where the firm produces monopolized products jointly and where it faces linearly decreasing marginal revenues. When the prices at which the products can be sold are decreasing linear functions of the outputs \( y_j \) such as \( p_j(y) = f_j - g_j y_j \), where \( f_j \) and \( g_j \) are positive constants, the revenue from the sale of the output vector \( y = (y_1, \ldots, y_m) \) is 
\[
\sum_{i=1}^{m} f_j y_j - g_j y_j^2 = (f_j y_j_1 - g_j y_j^2) + \cdots + (f_m y_m - g_m y_m^2).
\]

The inputs to the \( n \) production processes are assumed to be \( x_1, \ldots, x_n \) measured in monetary units. The input-output relations are assumed to be given by the linear equations 
\[
y_i = \sum_{j=1}^{m} b_{ij} x_j, \quad i = 1, \ldots, m.
\]
The sum of the \( x_j \) represents the cost of the production, so that 
\[
\sum_{j=1}^{m} (f_j y_j - g_j y_j^2) - y_j \lambda_j
\]
is the profit resulting from an expenditure of \( \sum_{j=1}^{m} \lambda_j \) on the production. The equations \( y_i = \sum_{j=1}^{m} b_{ij} x_j \) permit one to substitute for the \( y_j \) thereby obtaining the objective function in terms of the \( x_j \) alone. The \( x_j \) might need to satisfy linear constraints, such as (2). The result is then a linearly constrained maximization problem with a quadratic objective function, that is, a quadratic program.

Sometimes optimization problems arise in purely technical settings. For instance, it is often necessary to minimize the distance from a point \( \hat{x} \) to a set \( X \). When the measure of distance is the Euclidean metric and the set in question is defined through a system of linear inequalities, the resulting problem is a quadratic program with objective function:
\[
\sum_{i=1}^{n} (x_i - x_i^0)^2.
\]

**Convexity and Convex Programming** One of the most important concepts in linear and nonlinear programming is that of convexity. A set \( X \) is said to be convex if it contains the entire line segment between any two of its points. The line segment between the points \( u \) and \( v \) in a real vector space is \( \{x : x = \lambda u + (1 - \lambda)v, \text{ for all } 0 \leq \lambda \leq 1\} \). All polyhedral sets (1) are easily seen to be convex. A function \( f \) defined on a convex set \( X \) is said to be convex there if the inequality 
\[
f(\lambda u + (1 - \lambda)v) \leq \lambda f(u) + (1 - \lambda)f(v)
\]
holds for all vectors \( u, v \in X \) and all scalars \( \lambda \) satisfying \( 0 \leq \lambda \leq 1 \).
All linear functions are convex. A notable example of a nonlinear convex function is the quadratic function given in (5). The nonnegatively weighted sum of a finite number of convex functions is again convex. A concave function is one whose negative is convex. In minimization problems, it is desirable to have a convex minimand defined on a convex set, in which case the problem is called a convex program. (In the case of maximization problems, one would analogously prefer a concave maximand defined on a convex set. Such problems are called concave programs.) The main reason for this is that local minima (maxima) in convex (concave) programs are global minima (maxima). This property need not hold in so-called nonconvex programs.

**FIRST-ORDER OPTIMALITY CONDITIONS**

In all optimization problems, it is essential to have a clear, testable definition of what is meant by the (local) optimality of a candidate solution to the problem. Since LPs and NLPs normally have infinitely many feasible solutions, it is important to know what extra conditions must be satisfied by those that are (locally) optimal. In the case of linear programming—where the simplex method is used—one essentially has information that reveals whether passage from a particular vertex to any adjacent vertex will improve the objective function value. If not, the vertex yields an optimal solution. This information is obtained by checking the signs of certain numbers in the algebraic representation of the problem.

In nonlinear programming, the matter is far less simple. A major tool used for finding a local minimum is the following result.

**Theorem (Karush-Kuhn-Tucker Theorem)** Suppose \( \bar{x} = (\bar{x}_1, \ldots, \bar{x}_n) \) is a local maximum for the nonlinear program

\[
\begin{align*}
\text{maximize} & \quad F(x_1, \ldots, x_m) \\
\text{subject to} & \quad g_i(x_1, \ldots, x_m) \leq 0, \quad i = 1, \ldots, m \\
& \quad \text{and that the functions } F, g_1, \ldots, g_m \text{ are differentiable at } \bar{x}. \\
& \quad \text{If the gradients } \nabla g_i(\bar{x}) \text{ of the constraint functions at } \bar{x} \text{ satisfy a suitable regularity condition (one such being linear independence of the gradients), then there exist multipliers } y_1, \ldots, y_m \geq 0 \text{ such that}
\end{align*}
\]

\[
\begin{align*}
\nabla F(\bar{x}) &= y_1 \nabla g_1(\bar{x}) + \cdots + y_m \nabla g_m(\bar{x}) \\
y_i g_i(\bar{x}) &= 0, \quad i = 1, \ldots, m
\end{align*}
\]

Collectively, (7) and (8) are called the Karush-Kuhn-Tucker (KKT) conditions. Because \( g_i(\bar{x}) \leq 0 \) for each \( i \), the conditions (8) imply that at least one of \( y_i \) and \( g_i(\bar{x}) \) must be zero. Accordingly, these are called complementary slackness conditions. The stationarity condition (7) then says that, at a local maximum, the gradient of the objective function is a linear combination of the gradients of the constraints for which \( g_i(\bar{x}) = 0 \); the corresponding \( y_i \) are called generalized Lagrange multipliers.

It bears repeating that when the assumptions of the KKT theorem hold, conditions (7) and (8) necessarily hold. Since these assumptions do hold in most instances, the KKT theorem provides a mechanism for seeking candidate local maxima. In the absence of further hypotheses, it is not guaranteed that a solution of the KKT conditions will be a local maximum of the NLP. However, when the objective function and the constraint functions are all concave, a solution of the KKT conditions must be a global maximum of the optimization problem. In this instance, the KKT conditions are necessary and sufficient for the global optimality of \( \bar{x} \). Beyond the first-order optimality conditions given above, there exist second-order optimality conditions, but the discussion of such matters exceeds the scope of this entry.

**Lagrangian Duality** Relative to (6) with feasible region \( X \), there is the corresponding Lagrangian function \( L(x, y) = F(x) - \sum_{i=1}^{m} y_i g_i(x) \).

From the Lagrangian function, one defines the Lagrangian dual problem, which calls for minimizing the function \( \varphi(y) = \sup_{x \in X} L(x, y) \). An immediate consequence of this definition is \( \sup_{y \in X} \varphi(y) \leq \inf_{x \in X} F(x) \). If \( \varphi(y) \) where \( x \in X \) and \( y \geq 0 \), then \( x \) and \( y \) are optimal for their respective programs. R. Tyrrell Rockafellar’s *Convex Analysis* (1970) gives a comprehensive theory of duality for convex programming.

**Nonlinear Programming Algorithms** Nonlinear programs can differ greatly in the mathematical properties possessed (or lacked) by the functions through which they are defined. Examples of such properties include convexity and differentiability. NLPs whose constraint functions are affine, that is, of the form \( a_1 x_1 + \ldots + a_n x_n - b_i \), for \( i = 1, \ldots, m \), constitute a special class of which the quadratic programming problem is a notable member. Another property is that of problem structure: Some are very large and “sparse”; others are small and “dense.” A dense problem is one in which each of the functions actually depends on a high percentage of the total set of variables. Some nonlinear programs include (linear or nonlinear) equations among the constraints. The methods used to solve NLPs tend to take advantage of problem characteristics, and for this reason, differ greatly from one another. Even so, they share some common properties.

A common feature of mathematical programming algorithms is their iterative nature. Starting from a trial solution \( \bar{x} \), a sequence of trial solutions \( x^1, x^2, \ldots \) is generated until one of them, say \( x^k \) satisfies a specified crite-
tion indicating that it is an (approximately) optimal solution or that some other reason for halting the process holds. The steps of the algorithm constitute the process by which one passes from a given iterate to its successor. In some cases, this may entail the solution of one or more optimization subproblems. For linear programming and certain instances of quadratic programming, there are algorithms that generate a finite sequence of trial solutions ending with an optimal solution or evidence that none exists. Algorithms for nonlinear programming are more often convergent than finite. When the KKT theorem is applicable, the matter of finding a solution boils down to solving a system of equations (for which numerical methods are available). But before this can be done, it is necessary to try to identify exactly which equations need to be solved. The optimality conditions, and especially the information provided by Lagrange multipliers, play a large part in algorithmic strategies.

PROGRESS
Social scientists have historically concerned themselves with identifying patterns in the way people interact with their environment in order to account for factors that enhance both stability and change in society. This concern with the conditions that underlie the preservation and improvement of the human condition made the concept of progress—from the Latin progredior, meaning “a going-forward” or “advance”—an attractive analytical construct to the nascent social sciences in the nineteenth century.

While some scholars have traced progress back to classical Greece and Rome, most agree that, as an organizing concept in the social sciences, the concept derives its full meaning from specific developments in modern Europe. These included the growth of the physical sciences and theories of knowledge since the seventeenth century; the concern of eighteenth-century social philosophers with political, economic, and social reforms; and the influence of the biological model of evolution and a secular philosophy of history in the nineteenth century.

As early as the eighteenth century, the idea of progress marked a growing confidence in what many then believed to be the unlimited potential of science and human reason to create favorable conditions for improved human life. Following Auguste Comte’s positivism, which sought to extend the empirical method of the natural sciences to the study of social processes, progress came to epitomize the conviction that, as in nature, developments in society were regulated by innate laws. Through a scientific study of society, these laws could be deduced and their interactions with other social phenomena could be modified to ensure a desired social outcome. On the one hand, this meant that civilization was moving through cumulative stages of improvement so that even catastrophes like wars, epidemics, and earthquakes came to be viewed as temporary reversals, even necessary evils, in a movement to a happy ending. On the other hand, it implied that human beings, equipped with scientific knowledge, could alter this movement to influence the quality or quantity of the end product. Social institutions such as schools, prisons, and hospitals serve this purpose of complimenting natural laws to enhance the knowledge, morality, and health of members of society. In his The Idea of Progress: An Inquiry into Its Origin and Growth, Irish historian John Bagnell Bury (1861–1927) famously captured the optimism of this view by defining progress as the belief that “civilization has moved, is moving, and will move in a desirable direction” (1920, p. 2).

Most importantly, progress provided the social sciences with a rational solution to the old problem concerning the causes, mechanisms, and ends of social change. Where in earlier times change was generally dreaded and attributed to chance or supernatural intervention, it
would thenceforth be viewed positively as the outcome of processes that could both be predicted and objectively verified. There were ideological differences among social scientists concerning the mechanisms of social change. For social conservatives like Auguste Comte (1798–1857), change proceeded in an orderly manner through rational interventions by an elite class of social engineers, while for radicals like Karl Marx (1818–1883), change was attributed to class conflicts. This general understanding of progress as both law-governed and subject to human manipulation remained central in the social sciences up to the twentieth century.

Contrary to the atmosphere of optimism that attended the birth of modern social institutions, however, world events in the twentieth century gave rise to strong doubts about the desirability of the direction of human civilization. Two world wars, particularly the atrocities in Nazi Germany, and a succession of liberation wars in European colonies led to such intellectual and political criticism of progress that by the middle of the century the concept had lost its earlier luster. Thus, while in the 1930s sociology textbook series in the United States still included a volume on progress, by the late 1940s the historian Sidney Fay (1876–1967), in his article “The Idea of Progress,” would declare the concept “logically meaningless” (1947, p. 231). Even the first edition of the International Encyclopedia of the Social Sciences (1968) did not include progress as a separate entry.

Ironically, reconstruction efforts in the wake of the very events that led to the decline of progress invested a new set of concepts with some of the basic assumptions that the obsolescent progress had generated. The decolonization movements in the 1960s and 1970s fueled internal hopes for economic growth, self-determination, and social justice in the former European colonies. In this context, progress meant catching up with former colonizing countries by improving conditions of living through mass education and expanded social service. The economic plight that soon besieged these newly independent countries led to increasing interventions by international financial institutions like the World Bank, with the goal of encouraging growth-focused economic policies. New concepts like development, modernization, and structural adjustment moved in to fill the conceptual space vacated by progress.

CONCLUSION: WHAT WENT WRONG WITH PROGRESS?

Criticisms of progress both predated and outlived the calamities of the twentieth century mentioned above. They ranged from theoretical challenges of its analytical purchase to political denunciation of the social implications of some of the assumptions it had generated. One of these assumptions was aptly expressed by the Marquis de Condorcet (1743–1794), who declared in his Sketch for a Historical Picture of the Progress of the Human Mind that “the perfectibility of man is truly indefinite” (1793, p. 211). In itself, the notion that human beings can improve is not controversial. It is the idea behind educational institutions. However, the uncritical extension of scientific methods to the study of social life effectively reduced the diffuse and fluid interactions of everyday life to patterned behavior. If human behavior follows a determinate blueprint whose laws can be identified, does this mean we can socially engineer people to behave in certain ways and not others? In the context of fascist regimes and other forms of dictatorships in the twentieth century, the question was more than merely rhetorical.

Some philosophers and historians of science have also pointed out that science and reason are themselves not disinterested tools of knowledge but they can be used to perpetrate prejudice and domination. In the wake of Nazi theories of racial superiority, for instance, the earlier suggestion by the eugenicist Francis Galton (1822–1911) that social conditions could be created to ensure improved racial characteristics in future generations created fears of racial genetic profiling and contributed to the decline of eugenics as a science.

Cultural evolution, or the idea that whole cultures develop along a line of progressive improvement from barbarism to modern civilization generated the assumption that European cultures were at the apex of this cultural progress. On the basis of this assumption, European colonization of other people was often justified as a humanitarian mission to accelerate or guide their civilization. The idea, central to progress, of a universal history or of history as driven by a single universal norm also generated the assumption that people in other parts of the world existed outside history until the arrival of Europeans on their shores.

Another important aspect of progress was the emphasis on rationality and scientific thought, which put human beings at the center of social progress as its rational movers. Earlier critics of this humanist assumption had attributed social progress to nonhuman forces, such as the structured relations of social classes for Marx and the social division of labor for Émile Durkheim (1858–1917). In art, literature, philosophy, and social sciences, other critics have portrayed the human being as alienated, insecure, fragile, brutal, emotional, and as just one part of a complexly structured reality. Progress as an analytical concept developed in an environment in which men were generally assumed to be the standard bearers of the human species. Feminist critics have highlighted the fact that ideas about the “unity of humankind” and “perfectibility
of human beings” were held contemporaneously with practices and beliefs that denied political rights to women.

While progress generated some questionable assumptions, it also highlighted our collective capacity to improve the conditions of our lives. Among its advocates were people like the American philosopher and educator John Dewey (1859–1952), who emphasized that progress meant improving the efficiency of social institutions that are set up to meet the needs of all members of society.

PROGRESSIVE MOVEMENT

The Progressive movement is a broad label for the various economic, social, and political reform movements that took place in the United States between 1900 and 1914. Given the diversity among the reform efforts proposed or undertaken during this period, many scholars have disputed whether in fact this period should be treated as one common movement. It is true that many progressive Americans at the turn of the century supported a wide variety of reforms with different and sometimes irreconcilable goals. Nevertheless, the tendency to regard this period as a common whole is generally justified by the fact that the majority of reformers identified the same problems in America despite the wide variety of solutions they proposed. Throughout the Progressive Era, a common concern sets the tone for nearly every discussion of economic, social, and political policy: an uneasiness in the population brought about by the dramatic development of modern industry and the material and social changes it wrought in the lives of average citizens. Because of the substantial changes incurred from the emergence of large-scale mass production, the centralization of industry, the demand for greater specialization in labor, and the rise of new modes of transportation and communication, the landscape of the nation seemed suddenly transformed from a simple country of small, tightly knit communities into a complex giant of interspersed economic activities. In this new environment, the relationship of the individual to the broader economic, social, and political community took on an entirely new form.

As the United States entered the twentieth century, many progressives argued that the nation’s institutions and fundamental beliefs about the nature of government lagged behind the country’s dynamic economic and social growth. Railroad development had extended to nearly 200,000 miles and engulfed the nation in a dense network of trunk lines that had transformed its relatively autonomous communities and states into a single body of fluid commerce. According to many progressives, democracy had not kept pace with the national economic development of the industrial era due to its outdated understanding of federalism and the system of constitutional checks and balances. Many progressives thought that doctrines such as federalism, property rights, and separation of powers had rendered governments so inept that when state legislatures did pass regulations they proved harmful to both customers and the efficiency of business and industry, particularly railroad operations. Federal land grants to railroads and farmers during the late 1800s, made with very few contingencies out of deference to federalism, had led to reckless speculation by farmers and land owners, leaving the natural resources of the country in disarray. The rise of mass production in the steel, lumber, flour, textile, and meat industries had a major economic impact on the services provided by artisans, local mills, and jobbers, demanding an entirely new breed of legislation and regulation to handle the complex arrangements of modern industry.

The difficulty in regulating these corporations was most dramatically expressed in the case of United States v. E. C. Knight Co. (1895). Although E. C. Knight, a Philadelphia-based sugar-refining company, had consolidated nearly 98 percent of the nation’s sugar production, the U.S. Supreme Court held that refining was manufacture, not commerce, and thus could not be regulated under the interstate commerce clause of the U.S. Constitution. Distinctive to the Progressive Era was the belief that these obstacles to reform were not the result of temporary misjudgments by legislators or judges, but permanent defects in the institutional arrangements of American government.

From the political dilemma of government in a postindustrial age, progressivism developed along two lines: reformers bent on accomplishing concrete changes in the American system of government on the local, state, and federal levels, and intellectuals concerned with providing a revised notion of political life based on a new conception of human nature. As an intellectual move-
ment, the Progressive Era was an intensely active period of new ideas among a diverse body of thinkers from many fields of expertise. Despite their differences, almost all of these intellectuals raised doubts about the fundamental tenets of American political thought. In contrast to the fixed principles of human nature—the self-evident truths of equality and rights articulated in the Declaration of Independence—the progressives believed that a basic understanding of human nature involved a more fluid conceptual framework, such as the concepts implied in Charles Darwin’s (1809–1882) theory of evolution.

The impact of Darwin’s Origin of Species (1859) in social theory had raised serious questions about whether human beings were indeed created equal and endowed from birth with certain “unalienable rights.” Social Darwinists, as they came to be known, denied that human nature could be understood from such axiomatic principles, and some even challenged the fundamental political maxim that followed: governments derive their just powers from the consent of the governed. Enamored of the concept of natural selection and “survival of the fittest,” a new generation of scholars following the seminal work of William Graham Sumner (1840–1910) argued that political life ought to be geared toward the elevation of more talented individuals over less gifted or educated members of society, regardless of individual consent. Thinkers like the economist Irving Fisher (1867–1947), Sumner’s doctoral student at Yale, had even made the case for eugenics and the sterilization of the mentally infirm. Others, like John Dewey (1859–1952), while concurring with the basic premise of social Darwinism, contended that survival depended not on the elevation of certain individuals, but on a collective effort by all to overcome threats posed to the collective interests of the whole.

This theoretical debate over human nature had implications for the political direction of the reform movements. While some progressive intellectuals believed that the emergence of powerful corporations constituted a positive development, in which more-efficient entities capitalized on their superior capability over less-efficient organizations and modes of production, others argued that these corporations presented a challenge to the common welfare. Such a challenge could only be met by reforms in law and the country’s institutions of government.

THE ACHIEVEMENTS OF PROGRESSIVISM

While it is true that progressives never achieved the passage of constitutional amendments that equaled the breadth of their criticism, the movement did manage to spur a number of significant reforms at the local, state, and national levels of government. Such reforms sought to bring American government to a level of parity with the modernization that had taken place within civil society.

Municipal Reforms Progressivism was initially most successful at the level of municipal reform. Many American cities during the early twentieth century suffered from mismanagement and corruption. Under the control of party bosses and public utility magnates, city aldermen were often the stooges of special privilege rather than the guardians of urban health and safety. Through a series of reform efforts, urban dwellers managed to eliminate the most obtrusive corruption in their cities. Citing partisan politics as the main obstacle to triumph over corruption, many municipalities introduced such progressive reforms as the initiative, the referendum, and the Australian ballot to encourage greater civic participation and weaken the strong arm of political bosses. Other cities, however, took more dramatic steps during this period by replacing potentially corruptible politicians in city government with so-called nonpartisan experts in urban management.

These two approaches to municipal reform illustrate how the movement’s diverse and even contradictory efforts aimed at solving the same problems. Some progressives hoped to eliminate corruption through increased democratic methods, such as the initiative. Others embraced the new methods of scientific management codified by Frederick W. Taylor (1856–1915), author of The Principles of Scientific Management (1911), a work that spurred a movement for greater efficiency and expertise in all aspects of American life, including politics, as illustrated in such municipal reforms as the adoption of the post of city manager. While the above proposals differed, they shared the common view that democratic politics as traditionally practiced in the United States had led to corruption under the new demands of modern industrialism.

State Reforms Though less successful than municipal reformers, progressives at the state level could boast of major accomplishments in a number of states. As Wisconsin governor from 1901 to 1906, Robert M. La Follette (1855–1925) was probably the nation’s most ambitious progressive reformer, championing such state causes as railroad rate reform, procedural reforms in the legislature, progressive taxation, the open primary system, and the direct election of U.S. senators. William S. U’Ren (1859–1949) pioneered the use of the initiative, recall, and referendum in Oregon, while Hiram Johnson (1866–1945) in California successfully campaigned for the popular election for U.S. senators and to permit candidates to register with more than one political party. Other states achieved numerous reforms aimed at greater efficiency in the administration of state governments, particularly in the area of executive and bureaucratic reorga-
nization. By adopting higher standards for admission to civil service positions and organizing administrative offices in state government to attract greater expertise, many states were able to reduce waste and corruption, which had been an obstacle to the effective regulation of their economies.

Federal Reforms While progressivism did not produce the realignment in national politics that many political leaders had hoped for, the period did compile an impressive record of legislation at the federal level. These reforms would redefine relations between the national government and the country’s economy.

One of the most notable transformations in the role of the government in the nation’s economy began in 1902 as Theodore Roosevelt’s (1858–1919) administration pioneered the federal conservation reform movement under the Newlands Restoration Act (1902), which empowered the federal government to regulate the country’s natural resources with the help of experts in resource management. Like many progressive reforms, proponents of these changes also hoped to use the conservation movement as a means of introducing nonpartisan scientific expertise into the government’s management of the economy. Under Roosevelt, and later even more vigorously under Howard Taft (1857–1930), the trusts that had for years operated in violation of the antimonopoly provisions of the Sherman Antitrust Act (1890) were prosecuted by the federal government. By 1914 the Sherman Antitrust Act was strengthened by the passage of the Clayton Antitrust Act (1914), which prohibited discriminatory pricing, conditional sales intended to dilute competition, mergers and acquisitions that inhibit competition, and interlocking directorates. Like the reforms in conservation, the Clayton Antitrust Act was designed to incorporate nonpartisan expertise into the government’s regulation of the economy. To enforce the provisions of the Clayton Antitrust Act, Congress created the Federal Trade Commission (FTC) in 1914. The FTC would be staffed with five commissioners appointed by the president, with the advice and confirmation of the Senate. Rather than specifying the type of anticompetitive activities that would be prohibited, as the Sherman Antitrust Act had done, the FTC was granted the power to determine what kind of activity was harmful to the interests of the national economy, and could regulate accordingly.

Between 1903 and 1906 the federal government also made progress toward mitigating concerns over the power of the railroads and their discriminatory practices in favor of big business. In 1903 Congress passed the Elkins Act, which prohibited rebate schemes responsible for discriminatory shipping prices that angered economically disadvantaged farmers. In 1906 Theodore Roosevelt successfully negotiated the passage of the Hepburn Bill, which gave the Interstate Commerce Commission power to set maximum railroad rates. Besides remedial legislation addressing economic inequalities among the public, the federal government also began protecting the health and safety of consumers. Congress passed the Meat Inspection Act (1906), which required health inspections for food-processing plants, and the first Food and Drug Act (1913), which required companies to clearly label the ingredients and contents of their products.

Not only did government expand its reach within civil society during this period, it also released its grip on foreign trade, in contrast to previous regulations that had worked to the disadvantage of consumers. Under the administration of Woodrow Wilson (1856–1924), Congress repealed much of the tariff support for American industries with the passage of the Underwood Tariff (1913), which stripped many industries of the economic advantages they enjoyed under the former system. Although constitutional reforms fell far short of progressive aspirations, two important amendments were passed during this period. Both the Sixteenth Amendment establishing Congress’s power to legislate for an income tax and the Seventeenth Amendment for the direct election of U.S. senators were ratified in 1913. Establishing a progressive income tax fit the long-term reform goal of equalizing the burden of federal revenue and easing the sectional antipathy that had arisen from debates over the tariff. The direct election of senators satisfied the more democratic strain of progressivism, which aimed at introducing greater democratic participation into the choosing of the nation’s elected officials; reformers hoped that politicians who were beholden to party machines in state legislatures would be removed from office.

Despite its achievements, progressivism ultimately waned as a movement in the United States when the public’s attention shifted to the international concerns of World War I (1914–1918). Another explanation for the demise of the movement may have been its breadth as an umbrella for many different types of reform. Unable to identify a coherent purpose among the many ideas for political reform in the age of industrial modernization, progressives could not sustain the public attention necessary to effectuate a major realignment in American politics.

PROGRESSIVE TAXES
SEE Taxes, Progressive.

PROGRESSIVES
Progressives are people who strive to make government and society better—more democratic, more inclusive, and fairer. Toward this end, progressives engage in a broad range of activities aimed at reforming economic, social, and political institutions and processes. The term progressive encompassed a diverse and difficult-to-characterize variety of groups and ideologies. In general, progressives are activists who thrived during two periods in American history: The first progressive period ran from the 1890s to the 1920s; the second ongoing progressive period began in the 1960s.

THE PROGRESSIVE ERA
America’s first period of progressivism, known as the Progressive Era, came at the height of industrialization and urbanization in the United States. Although the goals and the types of reforms that progressives sought during this period differed, perhaps nothing characterizes the Progressive Era better than the impulse to reform. At the time, the United States was characterized by the increasing dominance of large corporations and political party machines, which progressives perceived as a threat to the American ideals of democracy and individual freedom. Corporate dominance inhibited the capacities of the vast majority of Americans to achieve social mobility, and urban-based political party machines were seen as corrupting the democratic process.

In response, progressives challenged laissez-faire ideology by arguing that good government could help solve problems. Progressives promoted, often successfully, a long list of reform legislation at all levels of government, including regulation of railroads, public utilities, and banks; laws protecting women and child laborers; and the passage of workers’ compensation and minimum-wage legislation. Progressives also worked for a progressive income tax; relief for the poor; a host of electoral reforms, including the direct election of senators, direct primaries, referendums, and recalls; voting rights for women; non-partisan election systems; civil service; and commission-manager and council-manager forms of local government. Such reforms aimed at strengthening popular sovereignty and produced significant and lasting results, even if some reforms did not lead to intended outcomes.

Progressivism had its roots in the populist movement of the late nineteenth century, as well as the struggles for equality for women and better living conditions for workers. Similar to the response of radical agrarian and working-class groups during the Gilded Age, progressives targeted many of the same problems wrought by industrialization, urbanization, and immigration: the spread of poverty, rapid financial and industrial concentration, and the oligarchic character of the political parties.

As the power of corporations expanded and social strife spread, middle-class social workers established settlement houses and other programs to ameliorate human degradation in city slums. Muckrakers, or investigative journalists, illuminated the corruption of corporate influence in politics and society. Religious groups promoted a social gospel that raised concerns about poverty, corruption, and the concentration of economic power and called on the moral conscience of the nation. Labor unions and workers organized to improve wages and working condi-
tions, and to make business more responsible through regulation. Women organized against child labor, in support of a minimum wage and a maximum number of working hours, and in favor of temperance. Even businessmen joined progressives in attacking political machines and promoting reform regimes. Thus, progressivism included professionals who undermined the foundations of laissez-faire ideology and promoted an ideal of public interest.

Yet progressivism was an uneasy coalition and not a cohesive movement. Progressivism during this period actually encompassed numerous movements for reform on the local, state, and national levels. These movements were diverse and sometimes even mutually antagonistic. Some progressives, such as socialists, sought fundamental change and structural reform to achieve social justice. Other progressives, such as middle-class professionals, strove for social order and more modest reform. Similarly, Protestant patrician reformers differed in their goals, approach, and sensibilities from Catholic, immigrant, and urban liberal progressives. There were also overtly reactionary groups involved in Progressive Era reform efforts, including eugenicists and antiblack and anti-immigrant groups. Thus, the Progressive Era was an ideologically fluid period where particular groups focused on different issues, and shifting coalitions competed to reshape American society. Despite their varying agendas, shared ideals of antimonopolism, efficiency, and social justice propelled and sustained the diverse progressive reform coalitions.

For example, new types of professionals—members of an emerging middle class, and members of religious organizations and business groups—pressed for reforms that focused on particular aspects of urban America. These progressives strove to undermine big-city political machines, which had in many cities retained the loyalty of immigrant working-class voters. Middle-class reformers regarded political machines as inefficient and corrupt, and they attacked the use of government resources as patronage—whether in the form of jobs for loyal party workers and supporters, or the distribution of municipal franchises, licenses, and contracts to favored businesses, sometimes in exchange for graft. Protestants attacked the tolerance of urban politicians for gambling, prostitution, and liquor, vices that offended middle-class sensibilities. The faith of progressives in scientific organizational principles led them to propose independent governmental institutions staffed by nonpartisan experts.

Labor and radical socialist groups attacked political machines for other reasons, such as the practices of allowing business groups to dominate economic policymaking and using police forces to break strikes. These socialist progressives fought to rein in corporate power and broaden government authority to improve education, expand social and municipal services, and advance social justice.

More often, however, progressive reform outcomes represented the interests of middle- and upper-class Americans. Middle-class reformers undermined working-class political power by backing the creation of independent commissions and boards that eliminated important powers from city councils and aldermen (city council members). These reformers also advocated the election of officials from neighborhood-based wards and the establishing of at-large schemes of political representation. Middle- and upper-class progressives also revised city charters and promoted new forms of government that shifted power to higher levels that they could more easily influence. Such reforms included implementing a commission form of government and a city-manager system. Some reform efforts during this period also reflected middle-class bigotry. Anti-immigrant groups, for example, were responsible for drastically reducing the flow of newcomers that could enter the United States and restricting the proportion of non-Western European immigrants allowed to enter. Advocates of eugenics employed pseudo-scientific methods in their reform efforts.

Despite the antibusiness stance of most progressives, they rarely questioned the basic structure of capitalist principals as vigorously as working and radical groups did. On the contrary, when the expansion of the public interest implied extending democracy to social as well as economic life, many progressives were ambivalent. Worker- and socialist-led movements, however, pushed the progressive critique further.

Politically, progressives allied themselves with particular factions of both the Democratic and Republican parties. Some progressive activists also mounted independent and third-party challenges. At the national level, progressives rallied behind Teddy Roosevelt (1858–1919) in 1912 as he ran for a second full term as president, this time as an independent under the Progressive Party (“Bull Moose”) banner. During his campaign, Roosevelt championed greater regulation of capitalism. In 1924 Robert M. La Follette Sr. (1855–1925), a U.S. senator from Wisconsin, ran for president as the Progressive Party candidate. La Follette, whose politics were more left wing, called for public ownership of the railroads during his campaign. Overall, progressives were more successful at the state and local levels, where they succeeded in electing members of the U.S. Congress, including Moses P. Kinkaid of Nebraska and Hiram W. Johnson of California, as well as scores of state legislators, and city officials.

The Progressive Era left an enduring legacy. Progressives promoted an ethos for harnessing government power to promote the public interest, which laid the
foundation for the active participation of government in solving social problems that would emerge during the 1930s and 1940s in the New Deal of Franklin D. Roosevelt (1882–1945). Many of the changes to law and government structures born during the Progressive Era remain in force at the beginning of the twenty-first century.

CONTEMPORARY PROGRESSIVES
Like their historical counterparts, the progressives who emerged during and after the 1960s criticize the concentration of economic and political power and engage in a broad range of activities aimed at making the economy more democratic and government more representative, responsive, and accountable. To achieve these goals, progressives fight against inequality and for social justice, and seek to foster ways ordinary citizens can more directly participate in decision making and self rule at all levels.

Contemporary progressives are associated with the social movements of 1960s, including the civil rights, Black Power, antiwar, youth, and countercultural movements, as well as later movements centered on women's rights, labor, the environment, immigrant and human rights, gay and lesbian rights, antiglobalization and global justice, and peace. Contemporary progressives often try to form connections among the various struggles, an orientation embodied in a popular slogan: “think globally, act locally.”

Many progressives embrace left-wing or radical ideologies, including Marxism and anarchism. Many contemporary American radicals prefer the term progressive because it is safer and more palatable than socialist and communist. Contemporary progressives contend that a better future is possible, and they strive to create a radically egalitarian, community-controlled world that meets human needs through environmentally sustainable development. They target multinational corporations and international institutions, such as Wal-Mart and the World Trade Organization (WTO), and they engage in a variety of tactics to achieve their goals, from lobbying and nonviolent civil disobedience to militant protest and out-right rebellion. Their efforts often incorporate new communications technology, and they have developed innovative strategies and political savvy.

In many ways, these contemporary progressive organizations model a progressivist vision in that they are comprised of many participants with few leaders. In addition, progressive coalitions embody groups that have not always seen eye to eye, including labor union members, immigrants, civil rights leaders, anti-sweatshop activists, environmentalists, human rights advocates, socialists and anarchists, and middle-class professionals. Progressives have spearheaded campaigns to achieve living-wage laws, advance public health, provide affordable housing, and protect the public sector and space. Contemporary progressives cross borders and continents, and are made up of participants from both the developing and developed worlds. They criticize the prevailing philosophy that governments should make way for the free market’s invisible hand, arguing that free trade is not always fair trade. In short, progressives attempt to think—and more importantly, act—beyond present-day predicaments, and they strive for a stronger democracy with greater citizen involvement in problem solving. Only then, they believe, will real equality and social justice be achieved.

Politically, American progressives have formed or allied themselves with various third political parties, including the Green Party, the Reform Party, and the Labor Party. These groups have supported such independent-minded candidates as Ralph Nader, Bernard Sanders, Paul Wellstone, Barbara Boxer, and Dennis Kucinich.

PROLETARIAT

The English word proletariat is derived from the Latin proletarius, first used in the sixth century BCE to designate a census category encompassing those without property,
who it was supposed could only contribute their sons to
the state (proles=offspring). The Latin term (and its equiva-

lents in other languages) came to refer to the poorest class
of nonslaves and to paupers. In the early nineteenth cen-
tury, however, proletariat began to acquire a more precise
meaning, and by the 1830s it was often used to refer to
the newly emerging class of wage laborers in capitalist
societies, formed by the expulsion of much of the peas-
antry from the land.

**MARX’S THEORY**

It is in this more precise sense of those who do not possess
their own means of production, and who must therefore
labor for others in order to make a living, that political phi-
losopher Karl Marx (1818–1883) began to use the term in the 1840s. Marx saw the proletariat as a
“universal class,” in the sense that its social position drives
it toward the overthrow of capitalist relations of produc-
tion, which he believed would bring about the end of all
forms of exploitation and oppression, and thus universal
human emancipation.

Marx wrote in the *Communist Manifesto*, “Society as
a whole is more and more splitting up into two great hos-
tile camps, into two great classes directly facing each
other: bourgeoisie and proletariat” (Gasper 2005, p. 40). The
bourgeoisie, or capitalist class, consists of the rela-
tively small number of people who own or control the
means of creating wealth—including land and raw mate-
rials; mines, factories, and offices; machinery and technol-
ogy—and who can employ wage laborers to work for
them. Proletarians perform most of the work in capitalist
economies, but they have little or no control over their
work-lives or over the wealth that they produce. The rela-
tionship between the bourgeoisie and the proletariat is an
exploitative one because the latter is paid less than the
value that its labor creates, with the surplus being kept by
the bourgeoisie. While wages may rise if workers are well
organized and during periods of economic growth, com-
petition between capitalists compels employers to reduce
labor costs as much as possible, particularly during recur-
ring periods of capitalist economic crisis.

During Marx’s lifetime, wage laborers constituted a
majority of the working population only in Great Britain,
some other parts of northern Europe, and the northeastern
seaboard of the United States, with the vast majority of
the world workforce still peasants engaged in small-
scale rural production. Today, by some estimates, wage
laborers are a majority of the world’s population. How-
ever, it was less its size than its structural and strate-
gic location that made the proletariat important for Marx.
Marx believed that antagonism with the bourgeoisie leads
proletarians to organize themselves into trade unions and
other forms of association. Because workers in modern
capitalism are concentrated in urban centers and in large
workplaces, they have enormous social and economic
power when organized, exhibited in their ability to bring
whole economies to a halt through the weapon of the
mass strike. By contrast, what Marx called the lumpenpro-
letariat (literally the proletariat in rags, i.e., those sections
of the population permanently or near-permanently
excluded from the workforce), lacks this power and is
therefore not a revolutionary class, although it is more
oppressed than the proletariat. Even where wage laborers
are a minority, their structural position gives them the
ability to draw wider social circles into struggle under
their leadership, including the majority of the peasantry.

In the course of the struggle to protect their interests,
proletarians are repeatedly led to challenge bourgeois
institutions (for instance, by ignoring legal restrictions on
strike action) and to question the general framework of
bourgeois ideas that confers legitimacy on the status quo.
As the movement develops, Marxist theory contends that
class-consciousness increases among workers and narrow
economic demands give way to broader political ones. At
the same time, divisions within the class—based on sec-
tional interests, nationality, race, ethnicity, and so on—
will tend to be overcome. If carried to a successful
conclusion, this process will culminate in the revolu-
tionary overthrow of the bourgeoisie. The proletariat will
replace the bourgeoisie as society’s ruling class and begin
instituting changes that will gradually lead to the elimina-
tion of class divisions entirely.

**CRITICISMS OF MARX AND THE PROLETARIAT TODAY**

Critics generally raise two kinds of objection to Marx’s
account of the proletariat. One is that the proletariat in
Marx’s sense has declined in importance as capitalism has
developed. It is certainly true that the structure of the
workforce in developed capitalist countries has changed
dramatically since the mid-nineteenth century, and the
proportion of factory and manufacturing workers has
been declining for decades. But while Marx often empha-
sized the role of the industrial proletariat, this is only one
segment of the capitalist working class, and as its relative
size has shrunk, the size of other segments has grown.
Moreover, segments of the workforce that had not previ-
ously been regarded as parts of the working class (such as
teachers and office workers), have found their work
increasingly routinized and controlled by their employers,
and have often unionized in response. It should also be
noted that on a global scale the number of industrial
workers is greater than ever, and that even in developed
countries they may continue to play a disproportionately
important role in the working-class movement.
The second objection is that wage laborers, at least in the advanced capitalist world, have benefited enormously from economic growth, and—even if still technically exploited—no longer have an interest in the revolutionary overthrow of capitalism, if they ever did. Contemporary Marxists acknowledge the large rise in living standards, although they are likely to emphasize the role of class struggle in achieving them and the fact that they are far from evenly distributed. More importantly, they argue that the gains should not be regarded as permanent, that capitalism is inherently unstable, and that its continued turbulence will bring about new economic, social, and environmental crises. On this view, it is because such crises are unavoidable, and because they will make life for the majority of wageworkers unacceptable, that the proletariat retains its revolutionary potential.

**PROLIFERATION, NUCLEAR**

Although recent events pose serious challenges to international efforts to limit the global spread of nuclear weapons, the nonproliferation regime is by many measures a great success. Despite pessimistic past projections that the world would by now contain twenty, thirty, or more nuclear weapons states, only three countries have joined the five nuclear weapons states acknowledged by the nuclear Non-Proliferation Treaty (NPT) in 1968 in openly declaring their status. As the cornerstone of international efforts to limit the spread of nuclear weapons, the NPT is unusual in two respects. First, in contrast to virtually all international treaties, it is discriminatory by design. The treaty recognizes and locks in inequality by regulating access to powerful weapons. Second, despite inequalities in rights and obligation, membership has grown to make the NPT the most widely ratified arms-control agreement in history, with 187 parties. In 2006, the only countries in the world remaining outside the treaty were India, Israel, and Pakistan (although North Korea declared its withdrawal in 2003). However, in recent years the regime has faced its greatest challenges, ranging from the potential emergence of new nuclear weapons powers to the apparent disinterest of the United States in the NPT.

**THE NUCLEAR NON-PROLIFERATION REGIME**

The impetus for the NPT grew out of dissatisfaction with the “Atoms for Peace” policies promoted by U.S. president Dwight D. Eisenhower’s administration during the 1950s. Under this program the United States offered unrestricted access to nuclear fuel in exchange for the promise that it be used only for peaceful purposes. The Atoms for Peace framework established the core bargain that would underpin the NPT: Countries that give up the military potential of the atom should be able to enjoy the full peaceful benefits of it. Oversight tasks were vested in a United Nations (UN) agency created to monitor Atoms for Peace transfers: the International Atomic Energy Agency (IAEA).

However, shortcomings in the Atoms for Peace/IAEA framework soon became apparent. By focusing only on nuclear materials transferred explicitly under specific agreements, the arrangement neglected to regulate technology, material, and knowledge developed indigenously (or copied from transferred material). At the initiative of the United States, Soviet Union, and United Kingdom, a new framework designed to monitor and regulate all nuclear material was negotiated. This became the nuclear Non-Proliferation Treaty, which opened for signatures in 1968 and entered into force in 1970. A grand bargain forms the core of the NPT: In exchange for forgoing nuclear weapons, nonnuclear weapons states gained access to technology necessary for nuclear energy and secured a commitment from the nuclear weapons states “to pursue negotiations in good faith” aimed at nuclear disarmament. The treaty thus strives to stem both horizontal proliferation (the spread of weapons beyond the five nuclear weapons states acknowledged by the treaty: the United States, Soviet Union, United Kingdom, France, and China) and vertical proliferation (by reducing the arsenals of these five). Article X of the treaty allows a party to withdraw from the treaty if “extraordinary events” jeopardize the “supreme interests of its country.” All other parties of the treaty and the UN Security Council must be notified three months prior to withdrawal. The NPT has a supply-side orientation aimed at regulating the use of nuclear technology, with relatively little concern for reducing the demand for nuclear weapons. To the extent that states
desire nuclear weapons to gain security and prestige, the NPT does relatively little.

SAFEGUARDS AND EXTENSION OF THE TREATY

The NPT established a set of international safeguards to obstruct the diversion of nuclear material and technology from energy to weapons programs. Administered by the IAEA, safeguards entail the monitoring and inspection of material and facilities declared by the signatory state. Iraq exposed the loophole in this arrangement by limiting its weapons-related activity to clandestine, undeclared facilities that remained outside the IAEA's inspection regime. To close this loophole, the IAEA obtained an expanded legal mandate in the form of an additional protocol providing inspectors with the authority to visit any and all facilities, declared or not. First available for signature in 1997, the Additional Protocol remains voluntary; members are encouraged, but not required, to sign. As of 2006, 78 Additional Protocol agreements are in force, and 110 states have signed them.

Although central to the treaty, safeguard arrangements are not backed by an effective enforcement mechanism. The IAEA itself can only suspend technical assistance to a country in violation of its safeguard agreements. To pursue stricter measures, the IAEA must refer a noncomplying country to the UN Security Council, which can choose to impose further sanctions. These range up to and include military intervention if action is taken under Chapter VII of the UN charter, which permits military intervention by other states in the face of a threat to international peace and security. However, the difficulty of achieving consensus in the Security Council—which includes each of the five nuclear weapons states (NWS) holding a veto—makes vigorous enforcement unlikely.

India’s “peaceful nuclear explosion” in 1974 exposed another weakness in the NPT-based nonproliferation regime by demonstrating that nuclear technology transferred for peaceful uses could easily be misused. In response, the United States proposed forming the Nuclear Suppliers Group (NSG), a group of nuclear technology exporters that seeks to control the export of nuclear materials, equipment, and technology. Growing from an initial membership of seven in 1975 to forty-five in 2006, the NSG has the advantage of including countries not party to the NPT (at the time of its origin including France, who, along with China was given NWS status but had refused to sign until 1992) and regulating exports to all countries. However, Pakistan's nuclear weapons program revealed two shortcomings in the NSG: National exports were weak at blocking transfer of subcomponents, and countries varied widely in the vigor with which they regulated exports.

In 1995 after month-long negotiations, the NPT extension conference adopted a motion to extend the treaty indefinitely. Although successful, the negotiations revealed divisions among members, most notably dissatisfaction among many non-nuclear powers at the limited progress of the NWS in reducing their own arsenals. Responding to these concerns, the conference adopted a “Principles and Objectives” calling for the completion of a Comprehensive Test Ban Treaty, the conclusion of a fissile material cut-off treaty, and the “determined pursuit” by the NWS of efforts to reduce nuclear arsenals. The extension conference also established a strengthened review process in which conferences to promote full implementation are held at five-year intervals. The first review conference in 2000 called once again for the “unequivocal undertaking” by the NWS of steps toward reducing their nuclear arsenals. Divisions among members had grown so great by the time of the 2005 review conference that members were unable even to agree on an agenda.

POST–COLD WAR CHALLENGES

The immediate aftermath of the cold war brought both peril and promise in terms of the spread of nuclear weapons. The collapse of the Soviet Union created three new nuclear powers overnight in 1991, as Belarus, Kazakhstan, and Ukraine inherited the nuclear weapons that had been stationed in their territories. Moreover, many scholars believed that the combination of security guarantees and restraint provided to their allies by the United States and the Soviet Union during the cold war had limited the spread of nuclear weapons. Removal of these guarantees and restraints, it was feared, might increase the demand for nuclear weapons. Finally, economic distress, rampant crime, and widespread corruption in Russia fed fears that some of its 27,000 nuclear weapons and large stock of weapons-grade uranium and plutonium would find their way to either terrorists or non-nuclear states.

Yet in the first years after the cold war, the promise seemed to outweigh peril. Belarus, Kazakhstan, and Ukraine all returned their weapons to Russia and joined the NPT. South Africa, which had accumulated a small nuclear arsenal, renounced its weapons and joined as well. France and China joined in 1992. And in response to the revelations of Iraq’s circumvention of the safeguard regime, NPT members strengthened inspections, established the Additional Protocol, and extended the treaty indefinitely. Finally, North Korea’s attempt to leave the NPT and acquire nuclear weapons appeared defused by the 1994 Agreed Framework accord with the United
States. Contrary to most expectations, by the mid-1990s there were still only five overt nuclear powers (although Israel, India, and Pakistan had unacknowledged weapons capabilities), the number of countries pursuing weapons was falling, and the NPT had become nearly universal.

CURRENT PROSPECTS
Recent years have seen new challenges emerge, exposing weaknesses in the nonproliferation regime. The decision of India and Pakistan to test nuclear weapons in 1998 heightened concerns about the three nuclear weapons powers that remain outside the NPT (although Israel does not publicly declare its nuclear weapons status, its nuclear capabilities are widely acknowledged). The three non-NPT nuclear powers are problematic because many countries joined the NPT on the belief that no other countries would openly declare nuclear status. If states successfully retain nuclear weapons outside the treaty, the incentives for members to exercise restraint become ineffective.

The apparent efforts of Iran and North Korea to pursue nuclear weapons from within the treaty pose an even more serious challenge. North Korea detonated a nuclear device in October 2006, and Iran is widely believed to be pursuing nuclear weapons. Both appear to be taking advantage of a key feature of the NPT: Countries can master the nuclear fuel cycle within the treaty and then withdraw to take the final steps in developing nuclear weapons. Obtaining weapons-grade fissile material—highly enriched uranium-235 or plutonium-239—is the only really serious obstacle to developing nuclear weapons. Yet the treaty facilitates mastery of the skills and technology necessary to enrich uranium and to separate plutonium from spent fuel. Once these tasks have been mastered, it is a short step from peaceful activities to producing weapons-grade material. The treaty thus bars countries from making nuclear weapons while providing them with much of the means to do so. Although this tension has long been recognized, no state appears to have pursued this path except North Korea and, perhaps, Iran. If North Korea and Iran acquire an open nuclear weapons capability, it may spur other countries to leave the NPT and also pursue weapons; Japan, South Korea, Saudi Arabia, and Egypt are frequently suggested as possibilities.

The revelation in 2003 that Pakistani nuclear scientist A. Q. Khan, who headed Pakistan’s nuclear program for almost twenty-five years, had been running a private proliferation network for the export of nuclear technology exposed further weaknesses in the nonproliferation regime. Most of the efforts to control the spread of nuclear technology, such as the Nuclear Suppliers Group, focus on stopping exports from the most technologically advanced countries. Yet the revelations that Khan ran a network selling everything from centrifuges for enriching uranium to bomb designs to Iran, Libya, North Korea, and perhaps a fourth country, raised fears that countries in the developing world with diverse capabilities could trade among themselves to bolster their nuclear programs, bypassing export controls. These fears prompted responses from both the United States and the United Nations. The United States announced the Proliferation Security Initiative (PSI), in which participating nations agree to forbid suspect shipments. With more than 70 countries participating by 2007, the PSI, unlike other controls, addresses technology transfer among developing countries. And in 2004 the UN Security Council passed Resolution 1540, which requires all members to establish export and transshipment controls over technology relevant to the development of nuclear, chemical, or biological weapons.

Discovery of the Khan network also heightened fears that nuclear weapons might fall into the hands of terrorist organizations. Similar private sector networks, poorly secured weapons and material in Russia, and North Korea are the most frequently cited possibilities as sources of atomic bombs for terrorists. Analysts are divided on the magnitude of this threat. Although nuclear devices would not help most terrorist organizations achieve their goals, terrorists with apocalyptic beliefs or those bent on meting out severe punishment to enemies may find them attractive, and evidence does suggest that Al Qaeda has a persistent interest (of debatable intensity) in weapons of mass destruction.

Although many of the challenges facing the nonproliferation regime suggest the necessity of revising the NPT, current policies of key states make that task difficult. Many see recent U.S. policies as retreats from commitments made at the 1995 review conference; these policies include the failure to ratify the Comprehensive Test Ban Treaty, the abandonment of the qualified no-first use pledge made by U.S. president Jimmy Carter’s administration to NPT members, and the persistent interest in new nuclear weapons designs. In addition, the U.S. invasion of Iraq is widely believed to have spurred proliferation by enhancing the appeal of nuclear weapons in the eyes of insecure regimes. Any bargain to reinvigorate the NPT would require commitment by the United States and the other four NWS to move forward on their commitments to disarmament, and most likely require some kind of agreement on the status of the three nuclear weapons states that remain outside the treaty. Given current policies, achieving agreement on reforms appears difficult, if not impossible.

PROPAGANDA

PROPAGANDA refers to the use of communication techniques to affect people's thinking and behavior. Any technique or action that attempts to influence the emotions, attitudes, values, beliefs, or actions of a group can be described as propaganda. Typically, propaganda benefits the sponsor and puts the interests of the sponsor above those of the recipient. As an instrument of persuasion and psychological coercion, it seeks to compel the recipient to submit to the will of the sponsor. Propaganda is thus different from education, which seeks to develop independent thinking, and from information, which is based on objective facts.

Many practitioners of propaganda have insisted that they merely transmit "education" and "information." Other euphemisms they use to describe their trade include "public relations," "public affairs," "public communication," "public information," "public diplomacy," "psychological warfare," "psychological operations" (or "psyops"), and "communication." At the end of the twentieth century the word spin became a popular and somewhat derogatory euphemism for propaganda.

Propaganda does not necessarily include lies, as many people believe. Often, propaganda involves truthful statements that are presented, or twisted, to serve the interests of the sponsor. In addition, propaganda is not always verbal: Although speeches, articles, leaflets, books, and rhetorical ploys are common forms of propaganda, so too are photographs, films, music, monuments, currency, flags, parades, and symbols. Propaganda also can include deeds—actions calculated to have an impact on the perceptions of others.

Today the word propaganda has a negative connotation, but originally it was a Latin term referring to the reproduction of plants and animals. It developed a positive religious association in the seventeenth century, when Pope Gregory XIII created a commission of cardinals (de propaganda fide) to spread the Catholic faith in foreign lands. In the next century some English speakers began to use propaganda to refer to the spread of political ideas, though not necessarily in a negative way. Many people continue to use the word propaganda in a political context, but propaganda need not be a product of a government or political organization. The advertising and public relations industries, for example, conduct propaganda on behalf of businesses and other nongovernmental organizations.

As a technique of persuasion, propaganda has been a feature of human life since the first civilizations were founded. The scope and intensity of propaganda, however, increased dramatically in twentieth century. As the communication and information revolutions gathered steam, governments, businesses, interest groups, and revolutionaries turned increasingly to propaganda to advance their agendas in a crowded marketplace of ideas. At the turn of the twentieth century many elite observers expressly advocated the use of propaganda as an instrument of social control. Theorists such as Gustave LeBon (1841–1931) and Walter Lippmann (1889–1974) issued alarmist warnings of a coming age of "mass society." Fearing that an uninformed public (which they called the "herd") would undo the social fabric of society, they suggested that elites should manipulate images and symbols to control the masses.

World War I marked an especially notable turning point in the history of propaganda. It was widely perceived as a "total war": an all-encompassing battle for national survival that demanded the mobilization of all the nation's resources. All the major governments involved
Propensity to Consume, Marginal

in the conflict developed propaganda bureaus to mobilize their publics for total war. The armies of the belligerents also developed sophisticated techniques of psychological warfare to demoralize enemy soldiers. Much of the war's propaganda consisted of wild exaggerations, crude images, and stories of atrocities. Warring governments played up nationalistic and patriotic sentiments while at the same time demonizing their enemies as barbaric savages. One of the most famous propaganda episodes of the war was a fabricated story circulated by British agents claiming that Germans were using human corpses to make soap. When the United States joined the war on the side of the Allies in 1917, President Woodrow Wilson added a peculiarly idealistic character to the propaganda by selling the war as a fight for democracy that would end all wars.

In the aftermath of World War I popular suspicion of propaganda as a technique increased, and many ordinary people came to use the word propaganda as a synonym for lies. The negative connotation was furthered by the conspicuous use of propaganda by totalitarian and fascist regimes in the 1920s and 1930s. The communist government in the Soviet Union, the fascist government in Italy, and the National Socialist regime in Germany all relied on propaganda techniques to come to power, to legitimize their rule, and to facilitate expansionist ventures abroad.

World War I also helped to stimulate the professionalization of propaganda techniques in democracies. The public relations and advertising professions ballooned into massive independent industries in the 1920s and 1930s. Most of the leaders in these fields developed their expertise working for government propaganda bureaus during the war. Additionally, more and more academic researchers began conducting serious social science investigations into the management of public opinion. World War II and the Cold War accelerated this trend by funneling money into the scholarly field of communication which emerged, in large part, from government-sponsored research into public opinion management.

Perhaps the most famous propagandist in history was Joseph Goebbels (1897–1945), who disseminated Adolf Hitler's doctrine of racial supremacy in Nazi Germany. But probably the most influential propagandist was an American: Edward Bernays (1891–1955), the so-called “father of public relations.” By his example and through his many writings—including the still-consulted Crystallizing Public Opinion (1923) and Propaganda (1928)—Bernays established the core principles that continue to be used in propaganda and public relations to this day.

Although the development of propaganda in the twentieth century was tied instrumentally to warfare and national security causes, propaganda techniques have become a reality of modern life. Few political leaders, celebrities, interest groups, businesses, and organizations go without an image advisor, public relations counselor, or spokesperson—all effectively “propagandists” working to advance the causes of their sponsors.

PROПENSITY TO CONSUME, MARGINAL

A marginal propensity to consume is, in economics, a change in consumption associated with a change in a factor that determines consumption. The most common use of the term is with respect to income. The concept stems from John Maynard Keynes's (1883–1946) General Theory of Employment, Interest, and Money (1936), Book III of which is titled “The Propensity to Consume.” Keynes defines the marginal propensity to consume as the change in consumption associated with a change in income (p. 115); later usage has differentiated a number of these propensities.

In elementary Keynesian models of the aggregate economy, the marginal propensity to consume from income determines the expenditure multiplier, the amount that total output will increase from an increase in autonomous spending (Keynes emphasizes this point in the General Theory immediately below his introduction of the term). If the marginal propensity to consume from income is nine-tenths, a one-dollar increase in autonomous spending will induce an initial increase of ninety cents in consumer spending and income; this ninety-cent increase in income will then induce a further increase of eighty-one cents in consumer spending and income, and so on. The sum of the increases in income will be ten dollars, or the product of the one dollar injection of autonomous spending and the inverse of one minus the marginal propensity to consume from income. Models
developed since the General Theory have attenuated the value of the multiplier from the very large ones suggested in the early analysis (in full employment models the multiplier will be zero); however, it is still the case that there will be a positive relationship between the multiplier and the marginal propensity to consume from income.

Given the central role of the marginal propensity to consume from income in Keynesian analysis, empirical work on measuring this variable started shortly after the General Theory appeared. Early examination of U.S. data, most notably those compiled by Simon Kuznets (1901–1985), suggested that the marginal propensity to consume from income in the short run was substantially less than in the long run. From the 1940s through the 1960s, three broad models of consumer behavior were proposed to explain this divergence. (1) The relative income hypothesis, proposed by James Duesenberry, argued that consumers are reluctant to change their living standards upon experiencing changes in income. Duesenberry maintained that consumption is partly affected by previous peak levels of income. Hence, the marginal propensity to consume out of income will be lower in the short run than in the long run. (2) The permanent income model of Milton Friedman argued that consumers recognize that a very large portion of income changes will be short-lived, or transitory, and will only change spending for those movements that are viewed to be permanent. In the long run, a higher share of income changes will be permanent. (3) The life-cycle model associated with Franco Modigliani (1918–2003) accepted the logic of the permanent income model but modified it to propose that the aggregate marginal propensity to consume out of permanent income would be affected by the distribution of income changes across age groups.

The distinction between the marginal propensities to consume out of permanent and transitory income became of significant policy interest in the United States in the 1960s and 1970s when a number of explicitly "temporary" changes in income taxes were enacted, and others proposed. Research suggests that the consumer spending impact from the enacted temporary tax changes was smaller than from "permanent" tax changes, in line with the idea that the marginal propensity to consume from transitory income is lower than that from permanent income.

More recent studies have noted the anomaly that the propensity to consume from temporary tax changes, while lower than from permanent changes, is considerably higher than theory would suggest. "Liquidity constraints" (the recognition that many consumers are unable to make the costless borrowing adjustments required for the strict permanent income theory to hold) are one plausible explanation for the high propensity. Other research has emphasized how precautionary saving motives—the need for many households to accumulate financial assets to insure against income losses—can affect the propensity to consume from income changes. The spending of households that need to accumulate precautionary savings will, in general, be more sensitive to purely transitory income changes than theory suggests, thus blurring the distinction between the propensities to consume from permanent and transitory income.

**PROPENSITY TO CONSUME FROM WEALTH**

The marginal propensity to consume from wealth is the partial derivative of consumer spending with respect to household wealth. The life-cycle model highlights the importance of wealth accumulation for retirement in the household spending and saving decision. This emphasis brought the wealth propensity to prominence. Movements in the value of wealth are, in principle, one-time events that will affect spending through the remainder of a consumer's life. Hence, the marginal propensity to consume from wealth is much smaller than that from income (less than one-tenth from wealth, seven-tenths or higher from permanent income), but given the enormous magnitude of changes in the value of aggregate wealth, even a small number raises the likelihood that major shifts in aggregate consumption could be generated.

The precise size of the aggregate marginal propensity to consume from wealth has been an active issue in the United States since the middle of the 1990s, given the increase in household wealth relative to income and the very large swings in market values. One line of research has emphasized that typically, a disproportionate share of changes in observed wealth (even some movements in wealth persisting for several years) are likely transitory. In other words, a large share of changes in observed aggregate wealth may not factor into consumer spending because households may not believe they will persist indefinitely. In particular, wealth movements that appear inconsistent with other economic developments, such as changes in income or productivity, could be regarded as transitory. Analysts and forecasters should not be assumed to have any special insight into the permanence of currently observed changes in the value of wealth. It follows that applying any estimate based on past experience of the aggregate marginal propensity to consume from wealth to project the spending impact of an observed movement in wealth may be problematic.

PROPENSITY TO IMPORT, MARGINAL

The marginal propensity to import is the increase in imports that is caused by a certain increase in income. This concept expresses the idea that as income of economic agents (firms and households) increases, so does their demand for intermediate and consumption goods imported from abroad. Since this relation also holds for the whole economy, at the aggregate level the marginal propensity to import can be calculated as the ratio between the increase in total imports of an economy and the increase in its output. In mathematically formalized economic models, the marginal propensity to import is equal to the partial derivative with respect to output in an import function. If imports are assumed to be a linear function of output, the marginal propensity to import is equal to the slope of the resulting straight line. The concept of the marginal propensity to import is related to the concept of the average propensity to import, which is equal to the ratio of total import to total income.

The marginal propensity to import plays a role in determining the size of the Keynesian multiplier (Blanchard 1997, pp. 232–235). In the Keynesian multiplier model extended to an open economy, some of the increased demand caused by a domestic expansion falls not on domestic goods but on foreign goods. This effect will be bigger, the higher is the marginal propensity to import of the domestic country. In the extreme case in which the additional domestic demand falls completely on imported goods (when the marginal propensity to import is equal to one), the multiplier is equal to one. Empirically, however, the marginal propensity to import is likely to fall between zero and one, which implies a multiplier larger than one even in an open economy. Since imports tend to be equal to a larger share of the economy for smaller countries, the magnitude of the leakage effect of domestic demand expansions into imports is likely to be inversely related to the country size.

An attractive empirical feature of the concept of marginal propensity to import is that it is easily measurable and can be used to forecast the change in imports stemming from a certain expected change in output. For example, if total domestic output in country \( A \) increases by 1,000 in a given year, and imports increase by 200 in the same year, the marginal propensity to import is equal to \( 200/1,000 = 0.2 \). Assuming that the government expects output to increase by 2,000 in the following year, the projected increase in imports calculated on the basis of the marginal propensity to import is \( 0.2 \times 2,000 = 400 \). This methodology is obviously based on the assumption that the marginal propensity to import remains constant. This might be a reasonable assumption in the short run. However, the size of the marginal propensity to import is affected by changes in the relative prices of domestic and foreign goods and could therefore change in the long run, or if the economy is hit by a significant exchange rate shock.

PROPENSITY TO SAVE, MARGINAL

In economics, a marginal propensity to save is the additional savings associated with a change in a factor that determines saving. Since saving is the difference between income and consumption, a marginal propensity to save is related to a marginal propensity to consume in a simple fashion. For example, the marginal propensity to save from household income is one minus the marginal propensity to consume from household income, and the marginal propensity to save from wealth is the negative of the marginal propensity to consume from wealth.

Any analytical result regarding marginal propensities to consume can be readily expressed in terms of marginal propensities to save. For example, in simple Keynesian analysis the autonomous expenditure multiplier is equivalently the inverse of one minus the marginal propensity to...
consume from income and the inverse of the marginal propensity to save from income.

In policy discussions and proposals, distinctions between national and personal saving should be kept in mind in applications of estimates of the marginal propensity to save and other arguments of the saving or consumption function. Numerous proposals have been offered to increase personal saving in the United States through tax or other fiscal incentives increasing the after-tax rate of return available to households. Discussions of these proposals often involve estimates of the responsiveness of household or personal saving to changes in the rate of interest, which is connected to the marginal propensity to save with respect to the rate of return. What is sometimes not emphasized is that a full analysis of these policies likely requires looking beyond the personal propensity to save with respect to the rate of return. For instance, such policies would likely increase after-tax personal income, and the marginal propensity of personal saving with respect to after-tax personal income is surely positive. This effect would add to saving generated through a positive rate of return propensity, or offset a decline in saving generated through a negative rate of return propensity. However, these policies (unless negated by other changes), will also increase government outlays or reduce tax revenue, thus reducing government saving. Hence, the effect on national saving of these policies would be problematic even if personal saving increased.

In sum, knowledge of the marginal propensity of personal saving with respect to the rate of return does not provide complete information about the effect on national saving of policies of this type. If the aim of such policies is to encourage saving by certain groups of people, or the policies are financed from tax revenues or cuts in government outlays, analysis of individual household responses would be adequate. But if the aim is to increase national saving and capital formation, and the policies are financed through increased borrowing, broader analysis would appear to be warranted. The parameters of interest will then be marginal propensities of national, not personal, saving with respect to its arguments.

PROPERTIES OF ESTIMATORS (ASYMPTOTIC AND EXACT)

Economic models are useful in making statistical predictions and policy evaluations. These models include statistical mean models, regression models, simultaneous equations models, limited dependent variable models, and panel and spatial models, among others. Based on the sample data, econometric methods are used to estimate these models, and then the testing of relevant economic hypotheses can be conducted. The commonly used estimators are least squares or generalized least squares, maximum likelihood, generalized method of moments, and empirical likelihood. The hypothesis-testing procedures are Wald's, Rao's score, and likelihood ratio methods. Since all these methods are based on sample information, the statistical properties of these procedures are of great interest for both small and large samples. The properties include studying the distribution; unbiasedness, which implies the average value of the difference between a sample estimator and the corresponding population parameter is zero; and efficiency, which means a smaller variability. For large samples, the estimators are consistent if they converge to their true parameter values. In the context of hypothesis testing, a test having a correct size and high power implies the probability of rejecting an assumed economic model when the model is true and not true, respectively. All these have led to the development of asymptotic theory econometrics (White 2001) and finite sample econometrics (Ullah 2004).

Asymptotic theory provides the properties of estimators and test statistics for large samples. The statistical methods used to develop such properties are the law of large numbers and central limit theorems (see Chung 2001). There is extensive literature on the asymptotic properties of econometric estimators and test statistics (see White [2001] for linear models; Jennrich [1969] and Gallant [1987] for nonlinear models).

Finite sample econometrics deals with the exact and approximate properties of estimators and test statistics. The exact properties are valid for any size of the sample; however, the derivation of the exact analytical properties is often difficult, especially for the large class of applied economic models that can be nonlinear, nonnormal, or dynamic. Furthermore, even when the analytical exact results are obtained, they are usually expressed in terms of complicated multivariate integrals or infinite series, and they do not provide meaningful interpretations and conclusions (see Ullah 2004). In view of these problems, a vast amount of literature has developed on the approximate analytical properties of estimators and test statistics.
using the procedures developed by Francis Edgeworth (1896) for distributions and Anirudh Nagar (1959) for moments. The simulation-based approximate properties have also been extensively analyzed, especially using bootstrapping procedures (see Hall 1992; Horowitz 2001). The analytical and simulation-based approximate results can tell us how much we lose by using asymptotic theory results and how far we are from the known exact results.

It is well known that large sample properties may not imply finite sample behavior of econometric estimators and test statistics, and this can give misleading results for small or even moderately large samples. For example, an estimator can be biased for the finite sample but unbiased asymptotically. Also, two estimators may be asymptotically unbiased and have the same variances and asymptotic distributions, but, in the finite sample case, these two estimators may have different biases, variances, and distributions. Thus the statistical inference for the asymptotic case can be quite different compared to the finite sample case. Also, if the asymptotic results are used for small samples, then the conclusions or interpretations of the econometric analysis may be misleading.

R. A. Fisher (1921, 1922) and Harald Cramér (1946) laid the foundations of statistical finite sample theory on the exact distributions and moments. This exact theory on distributions and moments was brought into econometrics by the seminal work of Trygve Haavelmo (1947), T. W. Anderson and Herman Rubin (1949), Leonid Hurwicz (1950), R. L. Basmann (1961), and Peter C. B. Phillips (1983), among others. Another major development took place through Nagar’s work (1959) on obtaining the approximate moments of econometric estimators. This was followed by research by J. D. Sargan (1975) and Phillips (1980), who rigorously developed the theory and applications of the Edgeworth expansions to derive the approximate distribution functions of econometric estimators. Most of the contributions, however, were confined to the analytical derivation of the moments and distributions of the econometric statistics with independent and identically distributed (i.i.d.) normal observations. These also included the finite sample results using the Monte Carlo methodology (Hendry 1984) and advances in bootstrapping (resampling) procedures (Hall 1992). The analytical and bootstrap results for models that are nonlinear with nonnormal and non-i.i.d. observations remain a challenging task for future development. Some development has begun to take place for approximate analytical results (see Ullah 2004; Bao and Ullah 2006). Similarly, there are developments in the bootstrapping procedures for studying the properties of estimators with i.i.d. as well as dependent and nonstationary observations (see Horowitz 2001).

The study of asymptotic and finite sample properties is a fundamental issue of statistical inference, since the quality of data-based inference depends on the properties of estimators and test statistics used in the inference. The developments described provide analytical and simulation-based procedures for the properties of estimators and test statistics. The frontier of this research area has moved forward over the years, but some challenging issues remain. With advances in computer technology, this subject will further develop in both the analytical and the bootstrapping domains.

**PROPERTY**

In the social sciences the concept of property or property rights refers to social mechanisms that control the use of valuable resources and create opportunities and incentives for private and public actors. Those mechanisms have profound consequences for social outcomes and over time are shaped by social outcomes. Many scholars, such as Douglass C. North in his 1990 *Institutions, Institutional Change, and Economic Performance*, use the terms institutions and property virtually synonymously. Modern social science has borrowed the concept from law but typically refers to real or de facto control of resources rather than formal legal or de jure control, which is the usual legal connotation. Law, moreover, gives property a narrower interpretation than does social science. In law, property is only one of several legal control mechanisms, which include tort law, criminal law, antitrust law, and constitutional law. In social science, property (or institutions) refers to all formal control mechanisms (rules and their enforcement) as well as informal ones such as social norms and ideologies.

**THE VARIETY OF PROPERTY RIGHTS**

A scarce resource or asset usually has mutually exclusive uses as well as compatible uses. A pasture cannot be used simultaneously as a shopping center, although various other uses are not excluded automatically. The grazing function of pastures often is not affected when aircraft use the airspace above, transportation tunnels are dug below, hikers cross the area on foot, and passing trains emit noise and vibrations. Property rights to a resource can be unified or partitioned by use.

A fundamental problem arises when a specific use of resource A interferes with the use of resource B by creating unwanted costs for the owner of B. Airplanes and automobiles often disturb the peace of homeowners, and factories pollute their surroundings. Uncompensated physical impact (known as negative or positive spillover or external effects) in principle is due to weak or absent property rights. Homeowners, for instance, have incomplete control (property rights) of the air they breathe and the sound waves that penetrate their residences.

Property consists of bundles of rights. In 1996 Elinor Ostrom and Edella Schlager identified five elements of rights to natural resources that appear in various bundles: access, rights to hike or canoe, for instance, but excluding rights to withdraw resource units; withdrawal, such as the right to catch fish or divert water; management, the right to maintain, improve, and transform a resource; exclusion, the right to decide who has access and withdrawal rights and how those rights are transferred; and alienation, the right to lease or sell exclusion and management rights.

Property systems vary with the ways in which categories of rights are divided and users and/or controllers are organized. The concept of public property has little meaning unless one identifies the exact bundle of rights, those who actually control the various elements, and the controllers’ incentives and opportunities. Similarly, by itself the term private property has little empirical content. Private property rights often are shared among independent private parties and delimited and restricted by the state. In law a privately owned corporation is classified as a legal individual, but the behavior of such entities depends on their internal organization and external constraints. Although their views are contested, as early as 1933 Adolf Berle and Gardiner Means in *The Modern Corporation and Private Property* drew attention to the possibility that shareholders, the formal owners, have limited control over their managers. Similar agency problems arise in public organizations that range from representative parliaments to nationalized industries.

The literature often confuses two distinct concepts: common or communal property and public domain or open access. Common or communal property involves arrangements by which a group of individuals jointly control access, withdrawal, and management rights to a resource such as a water system or pastureland. The usual defining characteristic of common or communal property is that the group lacks authority to alienate the resource to outsiders. Under appropriate circumstances common or
Property

communal property can be an efficient arrangement, as Elinor Ostrom showed in 1990 in *Governing the Commons: The Evolution of Institutions for Collective Action*. Property is absent, however, when a resource is in the public domain with no limits on withdrawal rights. This condition, which also is called open access, implies that no user has the incentive to maintain or improve the resource and invest in sustainable utilization. Lack of maintenance and unconstrained use eventually will dissipate the resource rent, as is happening in many high-sea fisheries. Open access conditions sometimes emerge in de jure property systems when the enforcement of private, public, or communal rights is weak.

**EFFECTIVE PROPERTY RIGHTS**

Property rights are said to be effective or efficient only with reference to specific goals. If the goal is to maximize the joint value of assets that belong to a social group (maximize wealth per capita), the community must minimize the sum of three cost categories: the costs of traditional production (transformation), exclusion, and internal governance. High exclusion cost sometimes rules out the option of dividing a resource such as the atmosphere, fish stocks in the ocean, or knowledge among individual owners and enforce exclusive ownership. Eventually new technologies and new types of organization may enable exclusion and, for instance, make possible exclusive ownership of individual fish in the oceans.

It is often efficient for independent actors to cooperate in utilizing a resource and share property rights if they can solve the problem of internal governance. The governance problem arises because opportunistic actors have a propensity to follow their self-interest and exploit their co-owner, for instance, by withdrawing more than their allocated share of units from a fishery or an orchard or failing to cooperate in doing maintenance work. Incentive schemes and direct monitoring are used to contain internal governance problems. High internal governance costs limit joint ownership, but new technologies and new forms of organization can lower those costs.

**THE EVOLUTION OF PROPERTY RIGHTS**

Recent studies indicate that the structure of property rights (institutions) is the fundamental explanation for long-term economic growth. In 2004 Dani Rodrik and coauthors provided empirical evidence for this proposition in "Institutions Rule: The Primacy of Institutions over Geography and Integration in Economic Development." The importance of property rights for economic progress raises two related questions: How do property rights evolve over time? Why do societies tolerate systems of property rights that cause economic decline?

Social science provides at least two perspectives on the evolution of property rights: the notion of unplanned or spontaneous evolution, which often is associated with the work of Friedrich Hayek, and planned or administered change, such as recent attempts at transition in Eastern Europe and in developing countries. Spontaneous evolution and administered change, however, need not be mutually exclusive. The history of the Soviet Union suggests that the general direction of change in property systems, for instance, away from or toward markets, often is administered centrally whereas the details and actual outcomes depend on spontaneous, decentralized interactions.

The state is the ultimate guarantor or destroyer of secure property rights. To finance projects such as warfare, powerful rulers and their cohorts throughout history have created uncertainty about investment projects by appropriating the wealth of their subjects. Stable property rights have emerged only when the balance of power has shifted against the rulers; that has occurred when social developments have increased the de facto power of groups such as feudal barons or a new middle class. Those groups sometimes have used their new strength to constrain the de jure power of the state, tie the hands of the ruler, and create limited government. These autonomous and path-dependent developments often are fostered by historical accidents. Dutch primacy in world trade and the Industrial Revolution in England were fundamentally not planned or administered events.

If flaws in the system of property rights are the root cause of economic decline, why do potential investors and producers not persuade their rulers to reform the system, expand the tax base, and share the fruits of growth? Failure to cooperate is caused by uncertainty about exactly who will gain materially from reforms, how reforms will affect future power relationships, and the high costs of making credible promises. When the state is not bound by strong judicial or other mechanisms, agreements between social groups and current or future rulers lack credibility. Political bargaining about property rules requires a balance of power and credible constraints. In addition to power relationships, social norms and ideology appear to play a role in the evolution of limited government.

**PROPERTY IN THE NEW ECONOMY**

A system of property rights is of great practical importance when the system fails to support advanced production technologies and wastes resources on a large scale. Large-scale failures are prevalent in developing countries and occur universally in the use of certain natural resources, such as the atmosphere. In a high-income country rapid technological change can undermine a previously effective property system and retard the country’s future development unless appropriate adjustments are made.
The new economy with its network industries and knowledge-based firms presents this type of challenge. Knowledge or intellectual property has replaced the plants and equipment of the Industrial Revolution as the engine of growth. Once they are made available, knowledge products have characteristics of public goods in that knowledge cannot be used up. In the new economy property regimes must balance two conflicting goals: giving scientists and technicians strong incentives to discover new knowledge and innovate and creating competition in the distribution of knowledge goods with output prices near the marginal cost, which often is close to zero.

The solution requires a difficult compromise. The initial creation of knowledge goods such as computer software and medicinal drugs entails high fixed costs, whereas the marginal cost of reproducing existing goods is often close to zero. Efficient intellectual property regimes must stimulate the supply of innovations by giving innovators an opportunity to cover their fixed costs while not allowing them to raise their prices so high that they limit the distribution of valuable products such as drugs. Various devices are used to create intellectual property, including patents, copyrights, trademarks, and trade secrets. In recent years the scope of patents has expanded, for instance, to include basic research in university laboratories. Some critics maintain that the use of patents and copyrights has exceeded sensible limits. Digitalization of knowledge and the rise of the Internet have worked in the opposite direction and undermined intellectual property rights, for instance, by lowering the cost of copying and distributing music and the contents of books.

For high-income as well as developing countries the lesson is the same: Economic progress depends on how each community adjusts its property rights to new technologies and new opportunities. The adjustment is determined in interactions between the state and powerful social groups, with the uncertain results depending on the balance of power, the structure of the political system, ideological beliefs, and available knowledge.

PROPERTY, PRIVATE

The institution of private property is one of humankind’s principal social arrangements. By defining and assigning legal ownership, property tends to promote the production, exchange, and accumulation of wealth. Property is especially lauded for the protection it is thought to provide against overbearing, arbitrary, and capricious government action. The institution, however, is more complicated than that laudatory view might lead one to believe.

Numerous theories of property have been formulated over the centuries. These are theories of the origin of property, the justification of property, the nature of property qua property, the evolution of property, the operation of the institution of property, and, among other things, how property interacts with other institutions. Some or many of these theories share a preoccupation with or defense of the received details of the institution. The typical argument is that the defense of a detail is instrumental to the defense of the institution as a whole. But these theories tend to be applied to different instantiations of property. If a proposed change in the law of property be
designated \( B \), then it is likely to be opposed insofar as it would change property provision \( A \); then, after \( B \) is adopted, and another change, \( C \), is proposed that will alter \( B \), \( B \) is defended in much the same terms as \( A \) was defended. The argument is to conserve existing rights. The same is true of multiple jurisdictions, the details of whose respective property institutions vary between them. The arguments used in defense of different existing sets of details are likely to be the same. To be in favor of property, therefore, is to be in favor of the results that the institution likely will promote. Whether a particular system of property is to include some detail is quite another matter.

One important implication of the foregoing is that different instantiations of property will yield different results. Putting it again formally, rights structure \( I \) will generate market structure \( I \) and demand-and-supply structure \( I \), and these in turn will result in resource allocation structure \( I \) and distribution (of opportunity, income, and wealth) structure \( k \); and similarly with rights structure \( II \) ultimately resulting in distribution structure \( II \). That is to say, there is no unique result, only results specific to the initial structure of rights, and so on.

One group of theories of property presumes that property is, or is derived from, the natural order of things. This presumption commits the naturalistic fallacy, namely, to intuit that because something exists it does so because it is either natural or derived from nature. This is fallacious in part because of the multiplicity of property systems and in part, indeed especially, because every property system is socially constructed, a product of human collective action, and not given by nature.

The institution of property is, for most practical purposes, the law of property, and the law of property is generated by government. Property is a mode of protecting interests, and any actual property system protects certain interests and not others. If \( A \) and \( B \) are in the same field of action and have conflicting interests, protecting \( A \)'s interest by law is substantively different from, but the analytical equivalent of, protecting \( B \)'s interest. To see that property is a mode of protecting interests enables one to see other aspects of property. One aspect is that property is not protected because it is property; property is property because it is protected. Another aspect is that litigation and lobbying are the means of promoting one's interests to be protected as property by either changing or not changing the law. A corollary is that the right to petition government about its protection of one's interests is a very important right; where one group has such access and another does not, it is more than likely that the former group will more largely and more effectively get its interests protected as property than the latter group. Another aspect of property has to do with regulation. If property is defined as antecedent to government (as in saying it derives from nature), then any regulation by government is a taking of part of that property. If property is defined as a product of government, then no such taking occurs: government is only changing the interest to which it is giving its protection. Thus, as a corollary, regulation may be formally identified as the protection of \( A \)'s interest against \( B \); in which case, so-called deregulation does not mean that government is no longer regulating. Rather it means that \( A \)'s interest is no longer protected against \( B \), and that government is now protecting \( B \)'s interest rather than \( A \). Such regulation (or deregulation) is a principal mode through which the law of property and therefore the institution of property changes.

Not all government protection of interests is designated property. What makes the institution of property so special is that a higher level of protection is generally thought to be given to interests protected as property than to interests not so protected, that is, protected as ordinary rights. For example, the right to be paid by one's employer in lawful money, or to have so many restrooms per hundred workers, or to have clean air at work (no more than a certain maximum of impurities and toxic elements) are rights that government can withdraw or change much more easily than it can change the property right to pollute; this is so even though the three specified rights may be seen as checks on property rights.

This latter point underscores another aspect of property: while the institution of property provides some measure of protection against government, that is, providing a check on the power of government, the government is itself a check on the power of property. This conflict is central to the institution of property and its evolution; what is important is what people are led to believe concerning which power should be checked. Moreover, determining which power needs to be checked by the other, and how, is largely a matter that is worked out by government, typically the courts. But such is only largely the case, inasmuch as voting for senators, representatives, and judges is in part a matter of providing citizen input into the process of whether \( A \)'s interest or \( B \)'s interest is to be protected or whether in a particular situation property owners or government itself is to be held in check.

Property, it is important to see, is relativist and is so in several ways. First, property rights are relative to the actions of the government that generates them. Second, property rights are relative to each other. And third, property rights are relative to the situation in which they exist. The economic significance of a right, therefore, is a function of: (1) the law that protects it relative to other protected interests; (2) others’ rights; and (3) the buying and selling activities, macroeconomic conditions, and other variables that comprise the economy. Competition itself is
a way of destroying the value of others’ property insofar as one competes to attract their customers to you.

The institution of property is so important not merely because of its status among other institutions, nor its function in promoting production and material well-being, and so on, but because of the decision making that goes into making and adjusting the rights that constitute property. Property is sometimes described through the analogy of a bundle of sticks. Each stick constitutes a potential ability to act or to be immunized against the consequences of others’ actions. This decision making is about who can do what to whom and has several dimensions. These are evident in the transformation of the economic system from one in which landed property had both economic significance and governance authority, to one in which both landed and nonlanded property, as well nonpropertied persons, participate in economic and political decision making. Apropos of the conflict between continuity and change, both small and large, or systemic, changes in property systems have taken place. Apropos of the conflict between freedom and control, the most fundamental changes are those that involve changes in the decision-making or power structure of the economy.

Also evident is the legal-economic nexus in which polity and economy do not simply interact but mutually help form each other. At the heart of both the transformation and the nexus is property and other rights as both cause and consequence. The total structure of rights constitutes the structure of decision making in markets and in government. Although rooted in the past, with decision making over changes in property keeping a selective eye on past legal precedents, seeking justice through continuity, the institution’s social function is oriented toward the future, in the encouragement it provides for economic activity and the structure given to that encouragement, as well as to the path to be taken by legal, social, political, and economic change. Not all sources of property need be normatively equal, nor are all property and other rights substantively equal.

action. Although the individual may choose to give up some property rights to society for the common good or in exchange for protections granted by society, classical liberals maintain that those rights are the individual’s to give up, not society’s to take.

**THE SOCIALIST POSITION**

Socialism begins with the position that it is the responsibility of society to ensure an equitable distribution of ownership. That obligation falls to society because, socialists believe, when individuals are left to their own devices, political and economic power become concentrated in the hands of the strong, who then exploit the weak. Thus, because it is the responsibility of society to protect all its members, property rights must belong to society as a whole. In the socialist framework the society bestows property rights on individuals to maintain equality of income and wealth.

The socialist position was greatly influenced by the exploitation of western workers in the late nineteenth century. The German philosopher Karl Marx maintained that workers had a right to the value of their labor and that a system that allowed employers to profit from the fruits of workers’ labors is destined to bring about the exploitation of those workers. Marxist socialists maintain that the way to avoid this exploitation of labor is for the state to own the means of production. Removing private ownership means that the government must decide how the means of production are to be used. This is accomplished by a central planning board that decides how much output industries will produce, what prices they will charge, and how much they will pay their workers.

Communism is regarded as the next evolutionary step beyond socialism. In the socialist system, the government owns the means of production only. Individuals still maintain ownership of their personal property. In the Communist system, the government keeps all property rights to itself and the individual owns nothing. In the Communist system, people work for no wage and receive everything they need from the government at no cost. What is common to the socialist and Communist frameworks is that property rights originate with society, not with the individual. Despite the use of the term, no modern country has ever achieved a Communist framework. Even those that have come closest, Russia, China, and North Korea, have not succeeded in attaining government control of all property. Modern examples of Communist systems are seen in religious communities whose members take vows of poverty. In these communities, the individual owns nothing but is granted use of property owned by the community.

**EXTERNALITIES AND THE TRAGEDY OF THE COMMONS**

Economists argue that it is important that property rights be well defined. When they are not, there is a disconnect between individuals who make decisions and individuals who must live with the consequences of those decisions. This situation is known as externalities and the tragedy of the commons.

In the case of externalities one individual imposes a cost on another that would necessitate compensation for the second individual if property rights were well defined. For example, a factory that pollutes the air imposes a cost on people who breathe the air. Because the factory does not bear the cost of pollution, it has an incentive to pollute more than it would otherwise. If property rights are defined so that those people own the air, the factory is forced to compensate them for the air it pollutes. The result is that the factory pollutes less. If property rights are defined so that the factory owns the air, people must pay the factory to pollute less so that the air will be breathable. Again, less pollution is created. Thus, when property rights are poorly defined, the economy produces more of the good than is socially optimal. When property rights are well defined, regardless of whom the rights are assigned to, the economy produces the socially optimal quantity of product.

The economic problem of the tragedy of the commons also results from poorly defined property rights. For example, if everyone in a village together owns a plot of pastureland (a commons), each person is free to graze his or her cattle on the land. However, because the ownership is spread over so many people, no single person has an incentive to maintain the land. The result is that the land will be overgrazed. However, if one person owned the land, that person would have the ability to profit from owning the land and therefore would have an incentive to maintain it.

A contemporary example of the tragedy of the commons is the treatment of endangered species. In countries that have outlawed the killing of elephants the elephant population dwindles because poachers have an incentive to evade the law and no one has an incentive to protect the elephants. Conversely, in the few countries in which killing elephants is legal, the elephant population is flourishing because people have an incentive to help the elephants thrive so that they can be harvested at a profit. As an extension of this example, cows are not endangered in the United States despite the fact that Americans consume millions of tons of beef annually. Because it is legal to own cows, farmers have an incentive to maintain herds and cull them at a profit. The decimation of the American buffalo, in contrast, occurred because cattlemen came to the plains before the rule of law was established. Without law to
enforce property rights, the buffalo were a common resource and so were hunted to near extinction.

PROPERTY RIGHTS, INTELLECTUAL

Intellectual property rights (IPR, or IPRs) are the rights of artists and inventors to get legal protection against unauthorized copying of their work. There are three main subtypes of IPRs: copyrights, trademarks, and patents. Copyrights apply to literary and artistic works, such as books, music, and computer programs; trademarks cover brand names, such as Coca-Cola®; and patents are awarded for new and useful inventions, such as the active ingredient of the molecule of a new antihypertension drug. In advanced industrial countries, IPRs account for an increasingly larger proportion of gross domestic product (GDP). In less developed countries, however, very little indigenous copyright-, trademark-, and patent-protected goods are produced.

Genuine IPR goods are often prohibitively expensive for citizens of the developing world. For example, in many countries in Asia and Africa, the cost of a computer software program is equal to the average per capita income. Thus, global income inequalities have given rise to a situation in which developing countries produce and consume illegitimate copies of IPR-protected goods. Usually, these goods are referred to as either pirated goods (for copyright-protected goods, such as software, books, and music) or counterfeit goods (for trademark- and patent-protected goods). The severity of piracy and counterfeiting varies, depending on the type of goods, the historical period, and the geographical location of goods. For example, the United States was notorious for not protecting foreign copyrights well into the twentieth century. Similarly, many African and Asian countries do not provide patent protection for pharmaceuticals. At the turn of the twenty-first century, software piracy and trademark counterfeiting are the best-known examples. According to estimates of the Business Software Alliance (BSA), in 2005 alone, $34 billion worth of business software was pirated worldwide. While copyright piracy poses no threat to consumers, some trademark and patent counterfeiting can have harmful effects on consumer health and safety. For example, fake (counterfeit) foods and medicines can lead to human death, while fake automobile parts have been linked to traffic deaths (Phillips 2005). One example of a counterfeit food is the “Sars” candy bar appearing in 2003, which is a counterfeit of the Mars candy bar.

How can IPR counterfeiting be eliminated? IPRs are protected both by national legislation and by various types of international treaties. In the United States, the 1976 Copyright Act, the 1946 Trademark Act (“Lanham Act”), and the 1985 Patent Act provide guarantees for the holders of IPRs. Most countries around the world have national laws protecting at least some types of IPRs. In addition, there are several dozen international IPR treaties. The main IPR treaties are the 1886 Berne Convention for the Protection of Literary and Artistic Works (for copyrights) and the 1883 Paris Convention for the Protection of Industrial Property (for trademarks and patents). The World Intellectual Property Organization (WIPO) in Geneva administers the Berne and Paris Convention, in addition to twenty-two other treaties covering the entire panoply of IPRs. Currently, WIPO has 183 member countries. Separately from WIPO, the World Trade Organization (WTO) administers the Agreement on Trade-Related Aspects of Intellectual Property Rights (TRIPS), which has been ratified by 149 countries. Despite the wealth of international agreements, however, there have not been radical improvements in the protection of IPRs in individual countries, and piracy and counterfeiting continue to exist around the world. This situation exists because international agreements are not self-enforcing and cannot be implemented without the will of individual national governments.

There are two mechanisms through which developed countries can compel developing countries to enforce international IPR agreements. The first one is the threat of trade sanctions. In the United States, the Omnibus Trade and Competitiveness Act of 1988 allows the U.S. Trade Representative to impose trade sanctions against countries that do not provide adequate IPR protection. Although virtually never imposed, the threat of trade sanctions can help sensitize some countries about the need to enforce IPR laws. This is a particularly powerful instrument against small states (e.g., Thailand) that are heavily...
dependent on trade with the United States. For bigger states, however, the threat of trade sanctions is not an effective mechanism for bringing about meaningful improvements in IPR enforcement. In such countries, the threat of withdrawing foreign direct investment (FDI) has proven to be a more successful strategy. For example, in China, the Quality Brands Protection Council (QBPC), representing more than 100 foreign companies with over $20 billion of investment in China, has been remarkably successful in lobbying the Chinese government to enhance IPR enforcement (Dimitrov 2004). Developing countries that invest in IPR, especially the development of indigenous patented technology, can be more competitive in the global economy.

In conclusion, IPRs protect valuable, yet often pirated products. Although multiple international IPR treaties exist, good enforcement depends on the will of domestic governments to implement them. When properly applied, foreign pressure can help sensitize the governments of developing countries to the benefits of providing stronger IPR protection.

PROSPECT THEORY
Prospect theory is a psychologically-based framework that describes the mental processes involved when an individual makes a choice among uncertain prospects. In the 1970s Israeli-born psychologists Daniel Kahneman and Amos Tversky (1937–1996) developed prospect theory along with a body of work that came to be known as heuristics and biases. The Nobel Prize committee singled out prospect theory when they awarded Kahneman the 2002 Nobel Prize in Economics, which he shared with economist Vernon Smith.

Prospect theory holds that people’s psychological makeup induces them to value the outcomes of decision tasks as either gains or losses relative to some reference point. Moreover, people tend to become less sensitive to incremental gains or losses, meaning that the additional sensation associated with either an incremental gain or loss is less than the previous comparable increment. In addition, losses are experienced more acutely than gains, a feature that Kahneman and Tversky called loss aversion. Taken together, the features just described give rise to a value function over gains and losses that is S-shaped—concave in gains and convex in losses. Moreover, the function features a kink at the origin, and is more steeply sloped for losses than for gains.

Prospect theory also holds that psychologically people overweight low probabilities and underweight probabilities whose magnitudes are moderate or high. According to prospect theory, a person facing a decision task evaluates each possible decision in the decision menu using a rating function. The rating function is a sum of products, where each product combines a value and an uncertainty weight. The decision that receives the highest rating is the one the decision maker chooses.

The S-shaped value function typically induces people to behave in a risk-averse fashion when the potential out-
comes involve only gains, and to behave in a risk-seeking fashion when the potential outcomes involve only losses. However, because of the weighting function, this pattern can be reversed when low probabilities are involved. Specifically, the weighting function can induce people to behave in a risk-seeking fashion when the potential outcomes involve only gains, and in a risk-averse fashion when the potential outcomes involve only losses.

When prospects involve a mixture of potential gains and losses, loss aversion will tend to induce people to act as if they are averse to risk. In particular, the kink at the origin of the value function leads people to exhibit a strong preference for certain outcomes over uncertain outcomes.

The manner in which a decision task is framed is known as framing. When people frame their decision tasks they are said to engage in editing. Prospect theory explains why people often frame complex decision tasks as sequences of simpler decision tasks, and then make decisions by applying value functions and weighting functions to each of the subtasks. In doing so, they might overlook connections among subtasks, and as a result choose inferior decisions, behaving as if they were throwing away money.

Prospect theory has had a profound influence on economic scholarship. It has been used to explain investors’ disposition to sell their winners too early and hold their losers too long; corporate managers’ reluctance to terminate losing projects; the equity premium puzzle about why the difference between the return to stocks and the return to bonds is puzzlingly high; why certain types of investors find cash dividends attractive; and why corporate managers appear willing to leave money on the table when their firms participate in initial public offerings. Prospect theory, especially the concept of loss aversion, has also had an impact on psychological research.

Prospect theory is a descriptive theory, unlike expected utility theory, which is the normative framework most commonly used in economic modeling. A comprehensive treatment of expected utility theory can be found in the Handbook of Utility Theory (1998). Whereas expected utility theory assumes that final wealth is the carrier of value, prospect theory assumes that change in wealth is the carrier of value. Whereas expected utility theory assumes that people are immune to framing effects, prospect theory assumes that framing has an effect on people’s choices. Whereas expected utility theory assumes that people do not distort probability values, prospect theory assumes that people overweight low probabilities and underweight moderate to high probabilities. Whereas expected utility theory assumes that people are uniform in their attitude toward risk, prospect theory assumes that people’s attitude toward risk is situation specific. Whereas the axioms that underlie expected utility are normatively desirable, experimental evidence suggests that in practice, people tend to violate some of these axioms, and instead behave more in accordance with prospect theory.

PROSTITUTION

Prostitution involves the exchange of sex for money or other material compensation. The most common type of prostitution involves women who provide sex to male customers.

Prostitution has a long history, and is sometimes called “the oldest profession.” It has not always been condemned and stigmatized. In ancient times, some forms of prostitution were viewed positively. Sacred prostitution, where a temple priestess had sex with men, was a way of worshipping the deity. In ancient Greece, prostitution was an accepted part of life. The highest-status prostitutes, the hetaerae, were valued for their intellect and companionship, and at their salons they entertained politicians, artists, and scholars. The hetaerae enjoyed much more freedom and mobility than other Greek women of the time.

PROSTITUTION AND GENDER RELATIONS

For most of history, however, prostitution has been condemned, and gender bias has been marked: Prostitutes have been blamed for a large number of social problems, but male customers and profiteers were rarely chastised. This double standard continues to this day.

Prostitution reflects larger, traditional gender relations between men and women. First, for the most part, it is men, not women, who typically pay for sex, which is an outgrowth of the broader worldwide pattern of objectification of women. Customers’ motives for buying sex differ, including satisfying a “need” for sex, inability to find
a conventional partner, desire for a certain type of sex or sex with a certain type of woman, fulfilling a fantasy, or engaging in risky behavior (Monto 2004). Second, reflecting women’s subordinate status in society, gender inequality is pervasive in prostitution. Female prostitutes are paid for their services, but often not under conditions of their choosing. For those who have male managers (pimps, brothel owners, etc.), the women have little if any control over their working conditions and are subject to significant economic exploitation.

Third, prostitutes are vulnerable to victimization, and this victimization is gendered. Male customers, pimps, and other men sometimes engage in violence and other types of abuse. A significant number of prostitutes report that they have been robbed, raped, or assaulted at some time in their career, and serial killers prey on streetwalkers. Because no study of sex workers is based on a representative sample, it is impossible to tell how frequently they experience violence, but it is clearly an occupational hazard. Customers are sometimes robbed and assaulted as well, but most of the victimization is directed at female prostitutes. Fourth, gender inequality is also the norm in the criminal justice system’s treatment of prostitution. Where prostitution is illegal, prostitutes continue to be arrested much more often than their male customers. Unequal justice is less pronounced in some cities than in others, and some cities periodically target customers but, overall, the police tend to focus on prostitutes (Weitzer 1999). Fifth, gender bias is apparent in portrayals of prostitution in the mass media. Films, television shows, popular music, and literature usually depict prostitution negatively, although it is occasionally romanticized. There are, of course, some realistic or sympathetic portrayals in popular culture, such as Sting’s 1999 song, “Tomorrow We’ll See,” but such depictions are rare exceptions to the rule.

INDOOR PROSTITUTION, STREET PROSTITUTION, AND MALE PROSTITUTION

There are exceptions to this general pattern of gender inequality. Not all prostitutes are exploited or victimized. Indoor workers who sell sex in brothels and massage parlors, as independent call girls, or as employees of escort agencies are less likely to be abused by customers than street prostitutes, and the indoor workers are also less economically exploited, express greater job satisfaction, and have higher self-esteem than their street-level counterparts (Vanwesenbeeck 2001; Weitzer 2005). Research shows that some indoor workers have quasi-romantic encounters with customers—not limited to sex but including conversation, cuddling, emotional support, and intimacy (Lever and Dolnick 2000). Indoor prostitutes are also less likely than streetwalkers to use addictive drugs and are at significantly lower risk of sexually transmitted diseases (Plumridge and Abel 2001). There is one important exception to this portrait of indoor prostitution: Women who are recruited by force or fraud and trafficked to work in brothels are at high risk for subsequent exploitation and victimization.

Gender inequality is absent in the case of male prostitutes, who sell sex to other men, who comprise a significant minority of the sex trade. Male prostitutes may be sexually objectified in the same way as female prostitutes, but compared to female streetwalkers, male prostitutes have greater control over their working conditions (few males have pimps); are less likely to have been abused as children, to be forced into prostitution, and to experience violence from customers; are more likely to enjoy their work overall and to derive sexual gratification from it; and are less susceptible to arrest or harassment by the police (Aggleton 1999; West 1993).

In sum, workers in different sectors of the sex trade, as well as male and female workers, experience different kinds of working conditions and varying degrees of victimization, exploitation, freedom, and job satisfaction. The type of prostitution is extremely important.

TRENDS

Today, the sex trade is a huge business worldwide, with numerous providers, customers, and third-party profiteers. Since prostitution is illegal in many places and stigmatized everywhere, it is impossible to determine exactly how prevalent it is or whether it is increasing, but a significant number of men admit to having bought sex from a prostitute. According to a 2000 survey, 17 percent of American men have paid for sex at some time in their lives, compared to 16 percent of Australian men (in 2001) and 9 percent of British men (in 2000). The real numbers are likely higher, given the tendency to underreport disreputable activity.

The Internet offers unprecedented new opportunities for sex workers to communicate with clients and set up appointments. Several major Web sites contain message boards that offer a wealth of information for customers: what to expect in terms of services and prices; “reviews” of a certain worker’s appearance, demeanor, and performance; and the offerings of specific establishments (e.g., a massage parlor, an escort agency). Customers’ chat rooms and message boards provide a fascinating window into the reasons why men buy sex, what they are looking for in a provider, norms regarding appropriate treatment of workers, and clients’ general views about paid sex and the sex industry.

Another trend is the growing internationalization of the sex trade. Sex tourism involves persons who travel from
PROTECTED MARKETS

A protected market is defined as one shielded from competition. The analytical concept dates back at least to Adam Smith, David Ricardo, Alfred Marshall, and other economists who analyzed the implications of imperfect competition, trade restrictions, and market power. Market protections may be natural or man-made, private or public, and welfare enhancing or depleting.

Some markets are naturally protected from competition by high costs of transportation because of distance, bulk, or terrain. A market isolated by high transport costs and characterized by economies of size so that only one firm can operate at low unit cost is called a natural monopoly. A cooperative form of business organization owned by patrons or government regulation of pricing has been used to avoid exploitation of producers and consumers in such naturally protected markets.

Naturally protected markets are the exception; protected markets more frequently emerge from deliberate action by firms, organizations, and government. Firms engage in exclusionary, predatory, and price-fixing behavior to create or exploit protected markets (Black 2002). Most nations have antitrust laws to avoid or counteract such exercise of market power. In the modern age of sophisticated science, technology, and information systems, firms turn to other strategies to protect markets. For example, a firm may protect its market by encouraging excessive standards (suited to the firm in question but not to other firms), by aggressive advertising, by exploitation of public ignorance (e.g., fear of chemicals or pathogens in tap water or in conventionally produced food), and by market power to expand shelf space in supermarkets.

In the case of organizations, workers form unions to protect their labor market from competition and so enable...
Protected Markets

collective bargaining to raise wages and improve working conditions. Workers in some countries have lobbied successfully for laws requiring large severance payments, long minimum wages and unemployment compensation, long vacations, short workweeks, and strict work rules. A consequence, illustrated by France, is high overall labor costs that discourage employment, especially of young, inexperienced workers. These factors coupled with racism and discrimination in French labor markets brought long-term unemployment rates of 20 percent or more among Muslim youth in the banlieue neighborhoods across France, sparking massive social unrest in 2005.

Turning to markets protected by government, border controls attempt to protect domestic workers from immigrant laborers willing to work for low wages and benefits. The result is salutary for domestic workers but hurts would-be migrant workers. Thus, policies to protect labor and industry can be divisive, creating a dual labor market of cosseted job-secure workers with generous benefit packages on one hand and poor unemployed and underemployed workers with limited future prospects on the other.

Governments of some countries pursue an infant industry policy or industrial policy by protecting selected domestic firms through tariffs, quotas, and regulation of competing imports while also promoting the firms with subsidies in the form of cheap credit, low taxes, and concessional access to public research and educational benefits. Such market protection is intended to help new firms until they attain the critical mass necessary to compete in international markets without assistance. A problem is that governments are not very adept at picking industrial winners. Target industries and firms are likely to be favored for political rather than sound economic reasons. Partly because market protection invites complacency in industry, favored treatment tends to be institutionalized and continued even after the favored industry was expected to mature.

Instruments such as tariffs, licenses, and regulations used to protect markets create economic rents—the stream of income generated over time by such instruments. Individuals, firms, and organizations have reason to engage in unethical practices, lobbying and bribing politicians and bureaucrats to create or remove such instruments. The consequence is corruption in government.

However, some market protections are justified and raise real national income. Firms that protect their market by being a first mover or by innovating faster than competitors serve consumers and raise national income. Market protection is useful in supplying public goods. In a laissez-faire competitive market, firms can recover only the marginal cost of their products. Hence, a firm is dissuaded from developing a new soybean variety, for example, because it cannot recover the millions of dollars spent to develop the seed. Governments award patents, copyrights, and trademarks so that firms can protect their intellectual property. Thus, firms can exercise market power to charge prices above marginal costs and pay for research and development.

Charging above marginal cost is a second-best policy. The first-best “textbook” policy in such cases is to rely on the public rather than the private sector to develop and pay for such technology. But governments do not have a favorable record, suffering from a dearth of funding and a surfeit of political misdirection in providing such public goods.

Society benefits from grades, standards, and sanitary and phytosanitary regulations that improve private market performance. Unfortunately, these and other market protections sometimes are employed to the detriment of society. The World Bank (Anderson et al., pp. 346, 351, 352) estimates that elimination of 2006 barriers (tariff and nontariff impediments not justified by sound science) to international trade in goods would add $278 billion to world income each year by 2015 and beyond—nearly half of that accruing to developing countries.

Public protection of markets often is justified to serve the environment (Southgate et al. 2007, pp. 103–123). Natural resources such as oceans, the atmosphere, and land are frequently open-access property inviting overuse. The consequent overexploitation of open-access property is called the tragedy of the commons. Uncontrolled access leads users to exploit resources “before the hoarders get them.” In 1960 Nobel laureate Ronald Coase pointed out that creation of property rights to such resources can align private with social incentives to achieve efficient resource use.

An example is the “cap and trade” market employed successfully to reduce sulfur dioxide emissions at low economic cost in the United States. The system begins with emission permits issued to each firm. The permits, which can be sold to firms or given to firms (reduced appropriately from historic emission levels), are negotiable. Firms that can reduce emissions at low cost sell their permits to firms expanding emissions to produce highly valued products.

In conclusion, prudent public policy to privatize, deregulate, and open markets at home and abroad has the potential to improve the quality of life around the world. In some cases that means opening markets, as in international trade. In other cases that means protecting markets, as in cap and trade systems for effluents or in patents for intellectual property.

Protectionism

Protectionism includes a broad range of obstacles created by governments to change the flows of international trade. A variety of policy instruments for trade barriers, including tariffs, quotas, and subsidies, has historically been used to protect domestic import-competing industries and to encourage exports. Occasionally, extreme measures such as a total prohibition of certain imports (bans) and sanctions are employed for economic or political reasons. Also, to avoid retaliation, or a “trade war,” strategies such as voluntary export restraints may occasionally be used. Broader restrictive measures that may be regarded as policies aimed at shaping the pattern of trade include: exchange-rate controls; the creation of monopoly power by establishing cartels, such as the Organization of Petroleum Exporting Countries (OPEC), to stabilize prices of raw materials; free trade areas, such as custom unions; most-favored-nations principles; relaxed property-rights protection; environmental standards; and imports certificates.

The effect of trade barriers on individual countries depends upon market structure in the world and the type of policy tools used. Protectionism in principle alters the allocation of resources, creating distortions and inefficiencies in production. While free trade as the rule of thumb is best, there are exceptions. For example, it has been argued that some trade strategies, such as temporary and targeted protection of key infant industries, may benefit the domestic economy in the long run, though the effects on the global economy are unclear. In fact, some of today’s industrial powers have benefited from such protectionist policies in the past. Similarly, the optimum tariff concept suggests that limited tariffs on imports may be advantageous to a nation, though world efficiency would diminish.

ANCIENT HISTORY

In ancient times, trade routes such as the Silk Road, the Spice Route, and the Incense Road were created and supported by governments to facilitate the exchange of goods between civilization centers in China, the Mediterranean, and Europe. During this period, raising revenue, rather than protection of domestic producers, was the primary objective of tariffs. For example, revenues from tariffs were used to build and maintain bridges and roads to make trade possible. However, China, between the late tenth and thirteenth centuries, maintained strict control over maritime trade by monopolizing exports, restricting trade to a few ports, imposing tariffs on imports, and regulating the purchase of traded Chinese goods. Trade was also a persistent issue in the relationship between Europe and the East. For example, the Crusaders banned trade with their Mediterranean foes, and only after conquering the eastern Mediterranean did they open it to European shipping.

In the sixteenth century, with the rise of nation-states, mercantilists introduced a formal analysis of winners and losers in trade and exercised protectionist policies lasting through the eighteenth century to accumulate gold and silver for armies. The mercantilists maintained that precious metals were the only things of value. In France, Jean Baptiste Colbert (1619–1683) brought all aspects of production under state control, including luxury goods, in order to improve industry in the colonial empire. To stimulate trade, the French government established an alliance with business by building and repairing canals and even subsidizing shipbuilders and shippers. Also, to defend French industry against foreign competition, Colbert imposed tariffs on imported cloth and subsidized the settlement of Dutch weavers into France. To discourage domestic consumption of exportable luxury goods, excise taxes known as sumptuary taxes were imposed. However, the extreme protectionist policies of Colbert did not bring prosperity to the French economy because the costs of such intervention exceeded the value of the benefits.

The protective trade policies of the mercantilists in Britain and Germany, on the other hand, were shaped by interest groups, wars, and recessions. For example,
Britain, Thomas Mun (1571–1641), director of the East Indian Company, maintained a state-supported monopoly over trade with India because of his lobbying power and influence in the Parliament.

MODERN HISTORY
At the start of the Industrial Revolution in the late eighteenth century, as belief in the protectionist policies of the mercantilists was dwindling, the views of physiocrats gained popularity. The physiocrats believed that land is the source of value and were the first to articulate free trade under their laissez-faire policy, according to which there should be no tariffs on the export of agricultural goods. Later, the English classical economists Adam Smith (1723–1790) and David Ricardo (1772–1823) rebelled against the mercantilists’ protectionist doctrine. Using the comparative advantage argument, Ricardo advocated free trade and attacked the corn laws, which limited the import of grain into England to protect domestic farmers. Assuming what was called later perfect competition, Smith viewed unconstrained expansion of markets through free international trade as a powerful force providing additional opportunities for specialization and the division of labor.

Although liberal trade policies gained prominence in the nineteenth century, some economists on both sides of the Atlantic questioned the assumptions of these free trade theories. They argued that in the presence of positive externalities and dynamic economies of scale, government must pursue activist national policies to promote economic development and industrialization. Among these economists, Friedrich List (1789–1846) of Germany is notable for the power of his argument and his historical exemplars—demonstrating how, alternatively, free trade or protectionism is useful, depending on the stage of economic development. In the nineteenth century, Hamburg was a major trading center benefiting from free trade, even as the largely agricultural economy of Germany was becoming overwhelmed by the industrial supremacy of Great Britain. List linked economic development and industrial growth to the national interest and security of Germany, and he called for elimination of internal tariffs among states and for the expansion of the custom union (Zollverein). He also pleaded for protection of infant industries with tariffs as a part of a broader development strategy that included other policies, such as the creation of a national railway network. List did not suggest a return to mercantilist policies; rather, he believed in the importance of manufacturing to the national economy. Living in the United States in the 1830s, List was influenced by the views of Alexander Hamilton (1755/57–1804), who, like List, was critical of protectionist policies such as corn laws and agreed with Adam Smith on national defense as a justification for protectionism. The infant industry argument was also supported by prominent contemporary economists, such as John Stuart Mill (1806–1873) and Alfred Marshall (1908–1993).

Historically, changes in economic theories seem to have motivated changes in government trade policies, though the direction of causation is not always clear. With the new ideological tool of laissez-faire, government policies moved toward more free trade during the nineteenth century. In the late nineteenth century, a revolution in shipping and an expansion of railways contributed to falling transportation costs, offsetting rising tariffs. The use of trade barriers rose during the twentieth century’s two world wars. However, after World War II (1939–1945), international organizations, such as the General Agreements on Tariffs and Trade (GATT), brought order to world trade by allowing a multilateral system of rules for government trade policies. During the oil and financial crises of the 1970s, protectionism tended to expand again in world trade. However, the Uruguay Round of the GATT trade negotiations led in 1995 to the formation of the World Trade Organization (WTO), which provides a forum for trade negotiations and dispute resolution among member states. The WTO has experienced some success in reducing trade barriers and reaching agreements in the areas of financial services, telecommunications, and information technology. In agriculture, however, reducing subsidies among developed countries has remained a challenge for the WTO.

PHILOSOPHIES OF PROTECTIONISM
While the old protectionism philosophy was concerned with attracting and retaining precious metals, modern protectionism theories are interested in the production benefits of restricted trade policies. Some of the new theories of international trade consider the consequences of economies of scale and relax the assumption of perfect competition. These theories question comparative advantage as the explanation for trade, and renew support for protectionism for national interests.

The historical pattern of government policy on international trade appears to exhibit cyclical movements between free trade and protectionism. The apparent systemic shifts between openness and protectionism are caused by a variety of factors, such as hegemonic stability emphasizing the importance of leadership. For example, in the second half of the nineteenth century, after Britain became the world economic and political power, it pursued an open economic system. U.S. leadership after World War II and the dominance of capitalism led to a worldwide reduction in tariffs by GATT. Other causes of changes in international trade policies include excess
industrial capacity and overproduction or a glut of agricultural products leading to high unemployment, declining profitability, and eventually protectionism, and developments of new economic theories, such as those by Smith and Ricardo. It is even argued that patriotic sentiments help shape protectionist beliefs.

**EMPIRICAL EVIDENCE**

Numerous studies since the 1980s examine various protectionist policies and their effects. For example, some studies have shown that the greatest growth in the world has been associated with the most liberal trade policies (Capie 1994; Baldwin 1986). However, since the late 1950s, some of the empirical evidence and casual observations have not been fully consistent with the simple theory of comparative advantage. In some cases, endogenous technological change, economies of scale, and imperfect competition have explained patterns of international trade better than the simple law of comparative advantage and have provided justification for government intervention. Strategic trade policies of export subsidies and import restrictions, targeting sensitive industries with increasing return and imperfect competition, have been successful in some countries in creating sustainable comparative advantage. However, economists such as Paul Krugman (1995) argue that the influence of interest groups on governments can lead to excessive and misguided interventions that are likely to raise national income but benefit only a small group of people. In other words, real world politics is as imperfect as markets. Typically, a small group of stakeholders in the protected industry benefit from protectionist policies, whereas the costs are distributed among a large number of consumers. Therefore, as Jong-Wha Lee and Phillip Swagel (1997) argue, while protectionism is inefficient economically, it may be efficient politically.

Gene Grossman and Elhanan Helpman (1994) produce a more rigorous analysis of protectionism and the role of interest groups. In their model, the structure of protectionism is determined by the elasticity of import demand, which determines the degree of welfare distortion and the ratio of imports to domestic output, showing the political significance of the domestic industry. Daniel Trefler (1993) carries this argument further by demonstrating that the level of trade protectionism is endogenously determined. According to the theory of endogenous protectionism, as import penetration rises in an industry, lobbying activities by interest groups intensify, leading to greater protection.

Investigating the determinants of trade barriers, Edward Ray (1981a) finds that tariff and nontariff barriers are the result of both economic and political factors. Ray’s cross-sectional study of U.S. trade finds that both the existence and intensity of nontariff barriers affect exports, though the profitability of protectionism depends on industry characteristics. Elsewhere, Ray (1981b) finds that industries with an apparent comparative advantage and with larger consumer losses tend to receive more protection in the United States. While tariffs are positively related to labor intensity, they are inversely related to the capital/labor ratio. Interestingly, the opposite is true for nontariff barriers. Furthermore, nontariff barriers are negatively related to seller concentration and geographical concentration, but tariffs are positively related to seller concentration and geographical concentration. Lee and Swagel (1997) accounted for country and industry characteristics and found that weak, declining, and politically important industries tend to receive more protection than exporting industries.

PROTEST
Social protest is collective action that uses unconventional means to press claims on institutional authorities to alter conditions and address collective grievances. From suicide bombings, to peaceful street marches, to religious ceremonies ordaining women as Catholic priests or acts of sabotage and passive resistance, social protests make claims on the state and other institutional authorities to correct perceived injustices, alter practices and understandings, and redistribute access to social goods. In the process, these protests also construct new collective identities and forge new meanings that inform politics and everyday life and bring about changes in popular culture, social practices, and institutional structures. While all protests are political in the minimal sense that securing desired changes typically requires gaining the cooperation and approval of political authorities, many protests are explicitly political in that they attempt to change public policies, the personnel in the government, and the structure of the state.

Protests vary in their visibility and methods. Everyday resistance is the most covert, involving acts of noncooperation, such as military desertion and foot-dragging by peasants, to more proactive acts, such as using symbols and gestures of authority to highlight discrepancies between how authorities act and their claims about what is fair and equitable (Scott 1985). Popular songs about exploitative bosses, as well as poetry highlighting the evils of landlords and heralding the heroism of the common people, put authority into question and prepare the way for more concerted protests. In Poland during the 1980s, for example, workers, artists, and intellectuals used the symbolism of the socialist state to question the extent to which the state actually represented worker interests, thereby paving the way for the demonstrations, vigils, and marches of the Solidarity movement (Osa 2003).

By questioning authority, everyday resistance may open the way to institutional protests that are overt, entail collective mobilization, and are legal or at least recognized by authorities as a legitimate form of expression. Initially, these protests are often illegal, but, through a process of accommodation with authorities and public acceptance, they become legitimized. By “striking their sails,” eighteenth-century sailors forced ship captains to pay back wages, distribute the “grog ration,” or put into shore. Later, the strike became a legally regulated form of protest, with government agencies responsible for certifying strikes and court regulation of picketing, marches, and the use of strike funds. In the 1770s early American colonists burned effigies and dumped tea into Boston Harbor, and organized widespread boycotts by refusing to pay new taxes imposed by the British Crown. Later, boycotts became legally regulated, and were split into primary boycotts (directed against the primary target) and secondary boycotts (directed against a third party, such as a grocery store that sells boycotted products).

Historically, forms of institutional protest were forged by excluded groups, such as industrial workers and racial minorities, who turned to protest when the conventional politics of voting and lobbying were unavailable or ineffective. Francis Piven and Richard Cloward (1977) argue that protests retain their leverage so long as they are illegitimate, but lose potency as they become regulated. In contemporary Western democracies, protest marches and demonstrations are mobilized by all types of groups, including corporations, churches, professional societies, and trade associations. Such protests have become legally regulated events, leading to the conclusion that Western democracies have become social movement societies (Meyer and Tarrow 1998). Sidney Tarrow (1998) argues that, by the early twentieth century, such institutional protests had become “modular” in that they are readily understood and available for most literate and media-conscious populations as a vehicle for expressing their interests.

Illegal or illegitimate protests that violate institutional rules and understandings are more disruptive and require more commitment. In such cases, protestors directly disrupt ongoing institutions by blocking access to them or impeding their routine operation and by directly defying authority. Nonviolent resistance or civil disobedience is one form of this category of protest. Drawing on Mohandas Gandhi’s (1869–1948) theory of passive resistance (Sharp 1973), in the early 1960s black college students organized lunch counter sit-ins across the American South, refusing to move until they were served and challenging authorities to arrest them until their demands for racial desegregation were recognized (Orum 1972; McAdam 1999). In the early 1970s in Northern Ireland, Irish Republican Army supporters staged hunger strikes in the prisons, refusing to cooperate with authorities and ultimately bringing into question the legitimacy of British policies and rule in the region (White 1993). Nonviolent resistance is typically framed in terms of a universal moral claim, such as “God’s law” or the “natural order,” that supersedes existing institutions.

All these forms of protest attempt to exert influence directly by imposing negative sanctions and creating uncertainty in the eyes of targets, and indirectly by mobilizing third-party bystanders to support demands for change. Protestors engaging in collective violence attempt
Protest

Protest has multiple causes. First are collective grievances, typically stemming from abrupt and widely experienced social strains or discontinuities that disrupt everyday life. Mass unemployment, political flight due to war and civil violence, and widespread hunger due to famine and political chaos are often critical. Second are resources, especially leadership and collective organization, that facilitate mobilization. More-cohesive groups that share collective identities and networks of solidarity, as well as experienced local leaders, are much more likely to protest. Black ministers and church leaders in the United States, for example, were central to organizing many of the civil rights protests of the 1950s and 1960s (Morris 1984). Third are cultural resources in terms of collective identities and understandings that can be used to frame and justify protest. Framing defines conditions as unjust and subject to change, thereby allowing groups to protest (Snow and Benford 1988). Fourth are political opportunities, that is, "the probability that social protest actions will lead to success in achieving a desired outcome" (Goldstone and Tilly 2001, p. 182). Electoral candidates faced with closely divided government and close elections make appeals to political outsiders in the hope that these groups might provide the votes needed for victory. In the United States, the closely fought national elections in the late 1950s and early 1960s made the black vote an appealing resource for both Republicans and Democrats, which encouraged civil rights protests by creating signals of governmental responsiveness (McAdam 1999). Similarly, these electoral contests helped trigger the farmworker movement of the 1960s, as well as a wave of student, women's, disabled, and other minority protests (Jenkins 1985).

Does protest create social change? Most protests fail in their broader objectives, especially as envisioned by critical intellectuals and activists (Rochon 1998). But protests nonetheless set in motion processes that often result in improvements for aggrieved groups. The labor protests of the 1930s helped create industrial unions, which became an important device for providing better wages, benefits, and job security for workers. Civil rights protests helped abolish Jim Crow laws and legal racial segregation, which characterized the United States through the 1960s, paving the way for black elected officials to introduce improved urban services in many southern communities (Button 1989). Anti–Vietnam War protests, especially the more violent and disruptive protests, helped push the U.S. Congress to adopt legislation limiting the war effort and eventually contributed to a reversal of U.S. foreign policy (Burstein and Freudenberg 1978; McAdam and Su 2002). These changes were not due simply to protests, but protests contributed to a broader set of political processes that have often generated policy and broader institutional and cultural changes. By initiating and stimulating these changes, protest can be seen as a rational and effective method of gaining political and social influence.

of the industrial west: a secular “spirit of capitalism.”
Adherents of this “modern economic ethic,” he argued, viewed work as a vocational calling (Beruf). Characteristic was a rigorous—an ascetic—organization of occupational life according to a set of values, a methodical and dutiful striving for profit and wealth, and a systematic reinvestment of money rather than its enjoyment.

THE DOCTRINE OF PREDESTINATION

The doctrine of predestination anchors Weber’s argument in The Protestant Ethic. According to the French theologian John Calvin (1509–1564), an inscrutable Old Testament God, omniscient and omnipotent, has determined that only a chosen few will be reborn into heaven. Good works or ethical behavior can never influence His decisions. Unbearable anxiety and fatalism were the consequence of this doctrine for the faithful, Weber noted. However, revisions were undertaken in the late sixteenth and early seventeenth centuries by the “Puritan Divines,” a group of Methodist, Calvinist, Quaker, and Baptist ministers, theologians, and lay believers in England. Herein lies the source of the Protestant ethic, Weber maintained.

Weber’s analysis at this point can be seen to divide into two stages. First, the Puritans elevated to the forefront methodical work and wealth. The purpose of life itself involved labor, they argued; work in a calling is “commanded to all” by God, and He is gratified by the active execution of His will by believers. Moreover, by taming base wants and desires, systematic labor assists concentration upon God and His plan; it also dispels the overwhelming doubt, anxiety, and sense of moral unworthiness caused by the doctrine of predestination. A parallel sanctification took place in respect to wealth. The creation of God’s kingdom constituted the purpose of this short life, according to the Puritans, and an earthly cosmos of wealth and abundance would surely serve His glory. Methodical work—a crucial means toward this noble end—thereby acquired a further special dignity. In sum, this ascetic Protestantism bestowed clear “psychological premiums” upon constant labor and the search for riches. Both activities lost their exclusively mundane meaning and became providential.

Although influential, this sanctification failed to overcome fully the long-standing ethos anchored in medieval Catholicism. Labor, according to this “traditional economic ethic,” was understood as a necessary evil, and profit was seldom earned honestly. If this “frame of mind” was to be banished, work and wealth had to acquire an even more comprehensive sanctification, The Protestant Ethic held. Furthermore, the all-important question to anxious believers—“am I among the

PROTESTANT ETHIC, THE

Published originally as two long articles in 1904 and 1905, Max Weber’s classic The Protestant Ethic and the Spirit of Capitalism (1920) is one of the most enduring and widely read volumes in modern social science. On its publication it immediately set off a heated debate and, remarkably, to this day the controversy has continued almost undiminished.

The Protestant Ethic investigated whether the “Protestant ethic” found among seventeenth-century Puritans (mainly Calvinists, Methodists, Baptists, and Quakers) “coparticipated” in giving birth to a driving force Weber (1864–1920) saw as contributing to the rise
saved?”—had not yet been answered adequately. In this regard, the second stage of Weber’s analysis proves crucial.

Despite the predestination decree, the Puritan Divines concluded that signs from God of the believer’s salvation status could be discovered. Above all, the deity’s favor seemed apparent if the devout demonstrated a capacity, as required by their vocational calling, either to labor systematically or to remain focused upon the onerous task of acquiring wealth. Indeed, the faithful convinced themselves that their strength and discipline to do so, as well as their intense devotion and righteous conduct, came from God: His energy was “operating within.” And surely this majestic divinity would bestow His powers only upon the predestined elect. Methodical work and great wealth now became “evidence” of one’s favorable salvation status.

FROM “SPIRITUAL FOUNDATION” TO “MECHANICAL FOUNDATION”

Now awarded psychological premiums in an even more thorough manner, constant labor and the possession of riches became viewed by believers as testifying to their salvation. They offered literal proof (Bewährung) to the devout of redemption. As anxiety declined, the depressed and bleak Puritan became transformed into the disciplined “tool” of God’s will, proudly engaged in the task of building His glorious kingdom on earth.

According to Weber, this methodical-rational organization of life and inner-worldly asceticism—a “Protestant ethic”—distinguished the “Puritan style of life.” The faithful focused their energies and conduct in a comprehensive manner upon God’s will, restricted consumption, reinvested profits, banished the traditional economic ethic, and placed work at the center of life. Extreme loyalty to His grand design marked the devout, as did cognizance that riches emanated from the hand of this omnipotent deity and thus belonged exclusively to Him and His kingdom. Wealth must be, on His behalf and for His community, invested instead of enjoyed. Simultaneously, the image of those engaged in business and oriented to profit changed: Rather than viewed as calculating, greedy, and self-interested, as had been the case since antiquity, capitalists were now perceived as honest employers engaged in a noble project given by God. The halo of religion—a “spiritual foundation”—surrounded their activities, and hence the understanding of the production and exchange of goods as involving exclusively utilitarian calculations and clever business procedures must be abandoned, Weber contended. Specialists in vocations—a new “type of person” (Menschentyp)—now embarked upon the stage of western history. They “coparticipated” in the formation of the spirit of capitalism and constituted one of its major “social carriers.”

Weber saw this “modern economic ethic,” which is represented in The Protestant Ethic by Benjamin Franklin (1706–1790), as providing an underlying psychological thrust and legitimation to modern capitalism’s early development in the eighteenth and nineteenth centuries. However, its value-oriented roots gradually died out as industrialization and urbanization proceeded over the last two centuries, and today capitalism unfolds exclusively on a purely “mechanical foundation.” Impersonal exchange relationships, pragmatic necessities, and manifold external constraint—a “steel-hard casing” (stahlharten Gehäuse)—now predominate. “The Puritan,” Weber maintained, “wanted to be a person with a vocational calling; we must be” ([1920] 2008, p. 123).

CRITICISMS OF WEBER

Controversy surrounded The Protestant Ethic immediately after its publication. Generations of critics and defenders have debated vehemently “the Weber thesis.” Arguably, no other volume in the social sciences in the English-speaking world has generated a more intense and long-term discussion. Four of the major lines of criticism are adumbrated here.

First, commentators have frequently viewed The Protestant Ethic as proposing that ascetic Protestantism caused, in a linear manner, modern capitalism. Innumerable critics then insisted that beliefs never explain historical change. Some maintained that new technologies introduced industrial capitalism (e.g., the cotton gin, the steam engine); others perceived the heroism and greed of great capitalists (e.g., Rockefeller, Carnegie, Vanderbilt) as pivotal; still others insisted that sheer business astuteness or the economic and political power and interests of a dominant class were central—and then argued that a systematic work ethos developed out of power and interests alone. All then dismissed The Protestant Ethic as naively trumpeting the power of ideas to change history. This criticism—“Weber is an idealist”—misses the mark, however. The Protestant Ethic acknowledged the necessity for a complex and multidimensional analysis ([1920] 2008, p. 125), yet Weber focused intentionally in this volume upon only “one side” of the causal configuration. He did so in order forcefully to bring a heretofore neglected cultural factor into an ongoing debate. Moreover, as noted, he sought to explain the origin of the spirit of capitalism rather than of modern capitalism.

Weber held in The Protestant Ethic that subsequent research must address the large question of whether the spirit of capitalism played a significant part in calling forth industrial capitalism. In fact, this broad theme—the unique development of the modern west out of arrays of “ideas and interests”—directly captured his attention in an ambitious series of comparative studies almost entirely
neglected by his critics. He asked, what constellations of interacting social, economic, political, technological, legal, and religious activities explain the particular historical pathway taken in the west? How can sociologists oriented to multiple causes analyze the specific direction and outcome of western history? *The Protestant Ethic’s* exploration of the religious sources behind the secular spirit of capitalism must be understood as Weber’s first step toward fulfilling this broad-ranging agenda.

Second, theologians in particular have been critical of Weber’s discussions of Catholic, Lutheran, and ascetic Protestant doctrines. Many have dissected Calvin’s teachings and failed to discover an emphasis upon work in a vocation. However, these scholars have neglected to note Weber’s distinction between Calvin’s doctrines and the ascetic Protestantism of the sixteenth and seventeenth centuries. He locates the source of the Protestant ethic in the Puritanism of this latter period rather than in Calvin’s teachings, and emphasizes the many revisions of Calvin’s thought introduced by the Puritan Divines.

Third, commentators frequently insisted that capitalism predated Puritanism. They discovered it to be significantly widespread in the ancient and medieval worlds in the west and Middle East, as well as in China and India. Although Weber maintained that his main concern in *The Protestant Ethic* involved the origins of a Protestant ethic and the extent of its influence upon a spirit of capitalism, capitalism’s general origins were also of interest to him. His discussion of this theme, however, distinguished sharply between modern industrial capitalism on the one hand and “political,” or “adventure,” capitalism on the other hand. Whereas the former—his interest—arose only in the modern west, the latter appeared universally, he held.

Fourth, a long list of critics argued that two Renaissance figures, the great entrepreneur Jacob Fugger (1459–1525) and the urban architect and aesthete Leon Battista Alberti (1404–1472), possessed a spirit of capitalism essentially similar to Benjamin Franklin’s. These commentators further maintained that the spirit of capitalism blossomed forth exclusively out of practical interests and utilitarian business astuteness. A religious source must be seen as both superfluous and historically inaccurate, they insisted.

Weber countered this attack in endnotes added in 1919 and 1920 to *The Protestant Ethic* by repeating and elaborating upon his defense against these “relativizing” critics. While noting that Alberti and Fugger had accommodated to, rather than changed, the economic conditions of their time, Weber contended that the central issue here involves a distinction—pivotal for him yet unacknowledged by the critics—between utilitarian activity on the one hand and value-oriented activity on the other hand. Motives vary, he emphasized, and the “practical-rational” approach to life is not dominant in all groupings in all historical epochs. This commentary, he maintained, neglected the ways in which values may independently motivate action. Indeed, a methodical aspect—an element indispensable for the birth of the spirit of capitalism and the shattering of the traditional economic ethic—was alone introduced by action oriented to values, according to Weber.

In sum, Weber often has been misunderstood by his many critics. A dynamic tapestry characterizes *The Protestant Ethic* analysis. Despite regular indictments, the Weber thesis survives to this day and must be confronted by scholars seeking to understand the rise of modern capitalism. By calling attention to the important historical roles played by both a Protestant ethic and a spirit of capitalism, *The Protestant Ethic* questions all those theories that explain the origin of the modern world exclusively by reference to utilitarian activity (for example, rational choice theory) or structural transformations (whether of Marxian or Durkheimian lineage). The varying subjective meaning of persons in demarcated groups proved central to Weber, as did the other-worldly, value-oriented ancestry of the modern world. The Puritan’s asceticism originated from his life “in but not of” the world.

*The Protestant Ethic* must be comprehended as the father of all schools of sociological thought that, in seeking to explain long-range social change, explicitly attend to cultural forces. It must be further understood as declaring emphatically that the past is interwoven with, and influences, the present. Finally, in an age of universalizing globalization, *The Protestant Ethic* conveys the causal significance of the indigenous cultural make-up inevitably manifest when a nation embarks upon an economic modernization course. He admonished social scientists generally to take account of religion-based background contexts for social change.

BIBLIOGRAPHY

**PROTESTANTISM**

Protestantism is generally thought of as being one of the three major branches of the Christian faith (the other two being Roman Catholicism and Eastern Orthodoxy). Protestantism is a broad category. It includes, for example, Anglicans, Baptists, Campbellites, Congregationalists, Lutherans, Methodists, Mennonites, Nazarenes, Presbyterians, Quakers, Seventh-Day Adventists, and Unitarians. Texts that are generally taken to embody the spirit of Protestantism include Martin Luther’s translation of the Bible into the German language, John Calvin’s *Institutes of the Christian Religion*, the Anglican *Book of Common Prayer*, John Milton’s *Paradise Lost*, Isaac Watts’s *Hymns and Spiritual Songs*, John Woolman’s *Journal*, George Eliot’s *The Mill on the Floss*, Søren Kierkegaard’s *The Sickness unto Death*, the *Barmen Declaration*, and the Rev. Dr. Martin Luther King Jr.’s *Letter from Birmingham jail*.

**HISTORY AND GEOGRAPHY**

Protestantism arose in Western Europe in the sixteenth and seventeenth centuries. It came into being as the result of the efforts of men such as John Calvin, John Knox, Martin Luther, Menno Simons, and Huldrych Zwingli to “reform” what they saw as the “errors” of the Roman Catholic Church. The drive to “correct” these “mistakes” ended up profoundly transforming the political as well as the religious, institutions of Western Europe. Indeed, scholars have claimed that the Protestant Reformation played a crucial role in creating the religious, political, social, economic, and cultural formations that came to embody “modernity.”

There is no scholarly consensus on the number of Protestants in the world. If one adopts a quite broad definition and counts people who are only nominally Christian as well as those who are quite devout, then one might argue that the total is over 800 million. Although Protestantism was created in Western Europe, it has spread throughout much of the world. Protestant beliefs and practices are quite common, of course, in Australia and North America, and have a strong foothold in some Asian countries—South Korea and the Philippines, for instance. Protestants make up sizable minorities in Latin American nations such as Brazil, Costa Rica, El Salvador, and Guatemala. In a number of African countries (Lesotho, Liberia, Malawi, Namibia, South Africa, and Swaziland, for instance), Protestants constitute a large proportion of the citizens. Indeed, some scholars have argued that Protestantism’s future may lie in Africa and Latin America rather than in Europe or North America. Certainly, it now seems to be far more vital in Africa and Latin America than in some of the nations of Western Europe.

**PRACTICES**

From the sixteenth century to the present, Protestants have consistently claimed to be highly suspicious of “empty ritualism.” Such suspicions notwithstanding, over the centuries Protestants have developed a set of powerful religious practices that vivify the doctrines and symbols of the Christian faith. Some Protestants (Lutherans and Anglicans especially) have maintained carefully crafted formal liturgies. The roots of those liturgies stretch back to—indeed reach back beyond—the sixteenth century, and have much in common with Catholic and Orthodox liturgies. Other Protestants, often referred to as Evangelicals, have created revival services intended to convert nonbelievers into devout Christians. And since the beginning of the twentieth century, a group of Protestants who are often labeled Pentecostals or Charismatics have held services that focus on the “gift of tongues.” This gift—which often results in a kind of ecstatic speech that is not intelligible to hearers—is thought of as a sign of the power of the Holy Spirit.

As a general rule, Protestants tend to display a strong love for singing hymns and gospel songs. Accordingly, a good portion of many Protestant worship services is devoted to choral and congregational singing. Protestant worship services also tend to devote a good deal of time to listening to homilies and sermons. These sermons, which are sometimes filled with emotion and sometimes quite erudite, are intended to help the people who hear them comprehend the truths of the Christian faith as those truths are set forth in the Christian scriptures.

Indeed, the importance of the Christian scriptures in shaping Protestant practice and belief is difficult to exaggerate. Reading the scriptures aloud is one of the high points of many Protestant worship services, and the hymns Protestants sing are often based on passages from the Bible. (Martin Luther’s “A Mighty Fortress is Our God” is, for example, based on Psalm 46.) The scriptures also play a large role in the private devotional practices of most Protestants. And Protestants greatly value Bible study groups and Sunday School classes in which small groups meet together to ascertain the meaning of passages from the Bible.

It is no accident that many Protestant devotional practices focus on the Christian scriptures, for Protestants have tended to see the Bible—rather than the traditions of...
the church—as the surest guide to understanding the nature of reality and of God. Protestants have often expressed a certain distrust of human reason or of observations of nature as a way to grasp the truth. If given a choice between relying on observations of nature, reason, tradition, or the Bible as a way to understand the nature of God and the universe, many Protestants would say, without hesitation, that their choice would be the Bible.

In part because they tend to put great confidence in the power of the Christian scriptures, correctly comprehended, to disclose the nature of ultimate reality, Protestants sometimes have acted in ways that have seemed to smack of hubris. In its most extreme form, this apparent hubris has resulted in some Protestant leaders coming close to asserting that the Bible is infallible and that they themselves have fully and correctly comprehended the truths that are taught therein. Critics have sometimes argued that this self-confident scripturalism is one of the hallmarks of Protestantism and that its predilection for that kind of scripturalism makes Protestantism a particularly dangerous form of religion. Such arguments are not without merit.

It should also be noted, however, that Protestants (like many other religious human beings) have sometimes been keenly aware of human finitude. This has sometimes led Protestants to fiercely critique all human attempts to speak for God and all human claims to have fully understood God’s nature and desires. Some Protestants have gone so far as to say that all human ideas and beliefs—including all Protestant ideas and beliefs—are very far from the mind of God. Under some conditions, the Protestant view of the world can, therefore, inculcate a good deal of humility within the people who adhere to it.

SOCIAL TEACHINGS

The Protestant tendency to see all human institutions as imperfect has sometimes been connected with a wide-ranging set of emancipatory impulses. Protestant beliefs and practices played an important role, for instance, in the abolitionist movements of the eighteenth and nineteenth centuries. Those beliefs and practices have sometimes been linked, too, with anticolonial and feminist movements. Many Protestants have, on occasion, fiercely criticized the behavior of the nation-states in whose borders they resided. Created in part in reaction to what sixteenth- and seventeenth-century reformers saw as an overly rigid and overly powerful set of ecclesiastical institutions, Protestantism has sometimes tended to value “freedom” over “tradition” and “conscience” over the “laws of men.”

Protestantism has also, many scholars would assert, served to naturalize a wide range of inegalitarian social relationships. In the eighteenth and nineteenth centuries, for example, Protestants wrote and preached countless defenses of the institution of chattel slavery. In the twentieth century, many white Protestants living in the United States (especially those living in the former slave states) advanced theological defenses of white supremacy. Indeed, pious Protestants often played crucial roles in Southern campaigns to defeat the civil rights movements of the 1950s and 1960s.

Patriarchal social relations have also often been naturalized by Protestant beliefs and practices. Protestants have generally thought of God as masculine and referred to God with masculine pronouns. Protestant churches have generally believed that to obtain salvation a woman must submit herself to the authority of this masculine Lord. Historically, women have been taught that it was “natural” for them to defer to men. Protestant churches have also tended to see persons who have sex with someone to whom they are not married as rebelling against God’s laws. Protestant churches have taught that women who have sex with other women and (especially) men who have sex with other men are violating God’s fundamental laws, and these sorts of violations have been regarded as particularly unnatural and repugnant. In general, Protestant churches have tended to be organizations in which heterosexual norms have been enforced quite strictly.

Scholars do not agree on the precise nature of the relationship between Protestantism and capitalism. Some scholarly analyses of that relationship (Max Weber’s, for instance) emphasize Protestantism’s role in creating circumstances in which modern capitalism could arise and flourish; other scholarly analyses (R. H. Tawney’s, for example) focus on ways in which the rise of capitalism decisively influenced Protestants’ assumptions and habits. Most scholars would, however, assert that Protestant churches have tended to naturalize the authority of capitalist institutions. Protestant churches have often seen commercial success as a sign of Godly favor and they have often acted as though it was natural for businessmen to play a large role in running church affairs. Protestant churches have eagerly adopted techniques and methods developed by businessmen. Indeed, many have been run in ways strikingly similar to those of for-profit corporations.

The “peace churches” (Mennonites, for example) have sometimes raised pointed questions about whether the violence employed by nation-states can be reconciled with the life and teachings of Jesus. But for the most part, however, Protestants have tended to see nation-states and nationalism as natural, even as ordained by God. They have been reluctant to challenge state authority even when it conflicts with Christian beliefs.

INTRODUCTION

A prototype is a representation that exemplifies the essential features of a category or concept. Specifically, a prototypical representation reflects the central tendency or the average or typical attributes of the members of a category. For example, the prototype of a table consists of the knowledge that a table has four legs propping up a flat surface. People store prototypical knowledge of social groups (e.g., librarians), objects (e.g., tables), events (e.g., dining out), and ideas (e.g., the perfect date). These prototypical representations facilitate people's ability to encode, organize, and retrieve information about everyday stimuli.

An early pioneer of prototype research was psychologist Eleanor Rosch, whose work during the 1960s and 1970s was inspired by the Aristotelian assumption that categories are logical entities whose membership is defined by an item's possession of simple matching features. Rosch argued that not all items within a category have an equal degree of membership—that is, that potential category members vary in their distance from prototypical exemplars. In short, category membership is not absolute but a matter of degree, and these differing degrees of membership have important implications for information processing. For example, people are quicker to agree with the statement “a robin is a bird” than to the statement “a turkey is a bird.” Moreover, people are more likely to remember statements that are conceptually prototypical (e.g., “the boulder fell down the mountain”) than those that are conceptually nonprototypical (“the lettuce fell down the mountain”).

During the 1970s and 1980s, Nancy Cantor and Walter Mischel extended Rosch's work on prototypes to the realm of social perception and social categories. According to Cantor and Mischel, there exist basic personality categories that social perceivers use to facilitate information processing about other people. This research was important in showing that people do not simply store specific, concrete items of information about others, but they routinely form abstract, prototypical representations. For example, when given traits about a person suggesting extroversion (e.g., friendly), people will later erroneously recall that they were given other traits (e.g., energetic) that fit the prototype of extroversion. These findings suggest that people are economical in their mental storage of information about others, relying on prototypes to influence the interpretation and accurate memory of specific personality trait information.

A concept in psychology that is related to the notion of prototype is schema. These two terms are often used interchangeably, but there are subtle differences. Prototype refers to a specific ideal image of a category member, with all known attributes filled in. For example, the prototypic “apple” may engender a representation of red, round fruit, even if actual category members vary so much on these characteristic dimensions that the prototype becomes meaningless for identifying them (e.g., some apples are green). An alternative to the prototype view of categorical knowledge is the concept of schema, which suggests that particular attributes can be ignored. For example, although we may associate “red” with apple, the schema concept allows for some features to remain unspecified. This greater flexibility with the schema concept may explain the wider use of the term schema, rather than prototype, in the social psychology literature.

Eliot Smith (1998) has argued that the distinction between schemas and prototypes is largely inconsequential and that four general points can be made about schema and prototype-based processing. First, schemas and prototypes are preexisting knowledge structures that are learned from other people or from experience. Second, the effects of schemas and prototypes on free recall tasks result from two sources: information processing that occurs at the time the stimulus information is first learned, and information processing that occurs when the information is later retrieved or reconstructed. Third, schemas and prototypes can be primed, thus influencing...
interpretations of information presented later. Finally, separate processes may govern our recall of specific traits and our overall evaluations of a person, rendering prototypes just part of the process of knowing others.

As Smith also has noted, psychologists in the twenty-first century have moved away from models of mental representations that portray knowledge units as static or stored in memory. In contrast, contemporary cognitive models view knowledge representations as active, interactive, flexible, and sensitive to context. The relatively new field of cognitive science, with its ties to computer modeling and neuroscience, promises to shed significant future light on the more dynamic role of prototypes in influencing phenomena at multiple levels of analysis, including neural, mental, and social.

PSYCHIATRIC DISORDERS
The 2000 version of the American Psychiatric Association’s diagnostic manual, the *Diagnostic and Statistical Manual of Mental Disorders*, 4th edition (termed *DSM-IV* for short), contains nearly 400 mental disorders, distributed across seventeen broad categories. These categories include childhood disorders, schizophrenia and psychotic disorders, mood disorders, substance-related disorders, anxiety disorders, eating disorders, sleep disorders, personality disorders, sexual- and gender-identity disorders, and impulse-control disorders. The number of mental disorders has ballooned from the first *DSM* edition in 1952 to the present, reflecting an increased “splitting” of broad mental illness categories into narrower ones.

**DSM-IV AND MULTIAXIAL FORMULATION**
*DSM-IV* describes individuals along five axes, or dimensions of functioning, the first two of which focus on what is conventionally regarded as mental illness. By providing users with a multiaxial formulation, *DSM-IV* aims to paint a reasonably comprehensive picture of each individual.

Axis I lists most major mental disorders, such as schizophrenia, mood disorders, and anxiety disorders. In general, researchers view these disorders as acute problems that are superimposed on individuals’ preexisting functioning.

Axis II lists personality disorders and mental retardation, which ostensibly differ from Axis I disorders in their greater persistence over time. Personality disorders are extremes of personality traits, such as impulsivity, dependency, and anxiety, that are inflexible, maladaptive, or both. Mental retardation is characterized by an IQ (intelligence quotient) of approximately 70 or below, severe deficits in adaptive functioning (e.g., inability to cook or dress oneself), and onset prior to adulthood.

Axis III lists medical conditions that can be relevant to individuals’ psychological functioning. Medical conditions can adversely affect the prognosis of many mental disorders and mimic the symptoms of many others. For example, hypothyroidism and stroke can produce the full clinical picture of major depression, a condition characterized by extreme sadness and loss of pleasure, along with such features as extreme guilt, sleeping and eating difficulties, and suicidal thinking.

Axis IV lists recent life stressors, such as death of a relationship partner or friend, and environmental problems, such as housing difficulties, extreme poverty, or inadequate access to mental health services. These psychological factors can precipitate or maintain mental illnesses. For example, research indicates that certain negative life events, especially those involving losses of loved ones, can trigger major depression in predisposed individuals. Evidence also suggests that schizophrenia, a condition marked by unusual thinking, delusions (fixed false beliefs), and hallucinations (perceptions occurring in the absence of any stimulus), can be triggered in some predis-
posed individuals by the stresses associated with poverty. Nevertheless, evidence suggests that causality also operates in the reverse direction because, for example, the deteriorating job skills associated with schizophrenia can lead to poverty.

Axis V describes the individual’s overall level of daily functioning. The inclusion of this axis acknowledges that people with the same psychiatric disorder differ markedly in their levels of adaptation to the environment. For example, some people with major depression are almost constantly bedridden, suicidal, or both, whereas others manage to perform surprisingly well in their occupational and family lives despite intense psychological pain.

**DEFINING PSYCHIATRIC DISORDER**

Theoreticians have long struggled with the question of what, if anything, all disorders of psychological functioning have in common. Although they have proposed numerous definitions of psychiatric disorder, all of these definitions have their shortcomings.

A subjective distress model posits that all mental disorders are marked by inner turmoil. Although many mental disorders, such as panic disorder (a condition marked by sudden surges of intense anxiety), are associated with subjective distress, some others, such as antisocial personality disorder (a condition marked by a long-standing history of illegal and irresponsible behavior) are associated with minimal subjective distress.

A statistical model posits that mental disorders are marked by statistical rarity. Although many mental disorders, such as infantile autism (a condition originating in infancy that is associated with serious deficits in language, social bonding, and imagination), are relatively rare in the population, others, such as major depression, are fairly common.

An evolutionary model posits that all mental disorders generate biological disadvantage, such as reduced life span or reduced ability to reproduce. Although some mental disorders, such as major depression, are associated with increased rates of suicide and therefore clear-cut biological disadvantage, others, such as specific phobia (an intense and irrational fear of an object, place, or situation), are not associated with any apparent reduction in lifespan or reproductive capacity.

In the 1990s Jerome Wakefield attempted to remedy these shortcomings by proposing that all mental disorders are harmful dysfunctions. According to Wakefield, all mental disorders (1) produce undesirable consequences for the affected individual, society, or both (harm); and (2) are characterized by the failure of a psychological system to perform its evolved function (dysfunction). For example, according to Wakefield, paranoia ("delusional disorder" in DSM-IV) is a mental disorder because (1) people with paranoia frequently experience marked distress, and (2) paranoia reflects a failure of the human threat system to operate properly. Specifically, in paranoia the threat detection system either reacts to nonexistent dangers or overreacts to mild ones. Yet the harmful dysfunction formulation has its limitations. In particular, some conditions, such as anxiety disorders, do not appear to stem from dysfunctions. Instead, in most cases these conditions seem to result from evolved systems reacting in adaptive ways to subjectively perceived threats.

In light of the problems with previous attempts to define disorder, some authors have proposed that psychiatric disorders are best conceptualized in terms of a family resemblance model. Just as brothers and sisters within a large family tend to look similar but do not share any single facial characteristic, mental disorders typically share a loosely covarying set of features. These features include subjective distress, statistical rarity, biological dysfunction, impairment, societal disapproval, irrationality, and loss of control over one's behavior. From this perspective, there is no “bright line” demarcating abnormality from normality, but rather a constellation of partly overlapping attributes that set most psychiatric disorders apart from healthy functioning.

**LABELING THEORY AND RESPONSES TO IT**

The mental illness concept has long had its harsh critics. Advocates of labeling theory, such as Thomas Szasz (b. 1920), have argued that diagnoses of mental illness are merely pejorative names that society attaches to behavior that it finds objectionable. In a 1961 book Szasz referred famously to mental illness as a myth, contending that what the mental health profession calls psychological disorders are actually “problems in living,” that is, difficulties in adjusting one’s behavior to societal demands. Many labeling theorists further contend that psychiatric diagnoses are culturally relative, because the behaviors that societies deem abnormal vary markedly across place and time.

Labeling theory has served a valuable function by reminding psychologists and psychiatrists that diagnoses are readily abused. Many nonscientific “diagnoses” in the popular psychology literature, such as sexual addiction, codependency, and road-rage disorder, are scant more than descriptive labels for undesirable behaviors. These labels yield little new information. For example, labeling an aggressive driver with road-rage disorder informs us only that this person frequently loses his or her temper while driving, a fact of which we were already aware.

Nevertheless, labeling theory’s critique of psychiatric diagnostic systems and the concept of mental illness falls
short on at least three grounds. First, many devalued behaviors, such as laziness, slovenliness, rudeness, and racism, are not mental disorders. Therefore, there is more to psychiatric disorder than social undesirability.

Second, many labeling theorists have overstated the cultural relativity of mental disorders. Admittedly, some mental disorders are specific to certain cultures. For example, koro, a condition characterized by a pathological fear that one’s genitals are disappearing, is localized largely to parts of Southeast Asia. Nevertheless, many major psychological disorders appear to be present across most, if not all, cultures. In 1976 Jane Murphy conducted a significant study of two societies that had experienced essentially no contact with Euro-American culture—a group of Yorubas in Nigeria and a group of Eskimos near the Bering Strait. These cultures had terms for disorders that were strikingly similar to several Euro-American disorders, including alcoholism, schizophrenia, and psychopathic personality, a condition marked by dishonesty, callousness, guiltlessness, and lack of empathy.

Third, many psychological diagnoses do more than describe already known behaviors. As Eli Robins and Samuel Guze observed in a classic 1970 article, valid psychological diagnoses provide us with novel information. For example, if we accurately diagnose an individual with bipolar disorder, formerly known as manic depression, we will learn several things about that individual that we did not know previously. Among other things, we will learn that this individual (1) experiences relatively sudden episodes of both mania (a condition marked by dramatically elated mood, energy, and self-esteem, along with poor judgment and impulsivity) and depression, typically punctuated by periods of essentially normal functioning; (2) is more likely than nonaffected individuals to have one or more biological relatives with mood disorders; (3) is at heightened risk for other psychological difficulties, including substance abuse and suicide; and (4) will probably respond positively to certain medications, such as lithium carbonate and antiseizure agents.

PREVALENCE OF MENTAL DISORDERS

Several large survey studies conducted in the 1980s, 1990s, and early twenty-first century have yielded valuable knowledge regarding the prevalence of major mental disorders in the general population. A 2005 study by Ronald Kessler and his colleagues revealed that between 25 percent and 30 percent of Americans suffer from anxiety disorders such as phobias, about 20 percent suffer from mood disorders such as depression and bipolar disorder, and about 15 percent suffer from substance-abuse disorders such as alcoholism. A surprisingly large proportion of Americans, perhaps 25 percent, also suffer from impulse-control disorders such as kleptomania (marked by recurrent stealing) and pathological gambling. On a lifetime basis, the most prevalent single disorder appears to be major depression, which afflicts about 17 percent of Americans at some point in their lives.

Survey studies also reveal important gender differences in the prevalence of some mental disorders. For example, in most populations major depression is about twice as common in women than in men. Antisocial personality disorder, in contrast, is about three times as common in men as in women. The reasons for these gender differences are unknown, but remain an active area of research investigation.

Race differences in the prevalence of psychopathology tend to be less pronounced than gender differences, although there are notable exceptions. For example, posttraumatic stress disorder, a condition marked by severe anxiety and avoidance reactions following a traumatic event (e.g., a rape, shooting, or motor vehicle accident), appears to be more prevalent in African Americans than in whites, perhaps because individuals in poor, inner-city areas, including many African Americans, often witness and experience traumatic events. Alcoholism is more prevalent in Native Americans than in other individuals, probably for a mixture of genetic and environmental reasons, the latter including poverty and alienation from the broader American society.

CAUSES OF MENTAL ILLNESS

The past several centuries have witnessed a variety of approaches to the etiology, or causation, of psychiatric illnesses. Etiological models of psychological disorder have shifted over time in accord with prevailing societal conceptions.

During the Middle Ages many people embraced a demonic model, which viewed mental illnesses largely as the product of evil spirits infecting the mind. Not surprisingly, exorcism was often the preferred “treatment” of the day. In succeeding centuries, conceptions of the causes of mental disorder became progressively more rooted in naturalistic as opposed to spiritual explanations.

Psychodynamic approaches, originated by Sigmund Freud (1856–1939) and his followers, place substantial emphasis on the role of early life experiences, unconscious influences, and psychological conflict in the genesis of mental disorder. For example, psychodynamic theorists might view obsessive-compulsive disorder, an anxiety disorder characterized by repeated intrusive thoughts (e.g., fears of contamination) and by unsuccessful efforts to neutralize them (e.g., frantic cleaning), as an unconscious psychological defense against deep-seated fears of loss of emotional control. These fears, in turn, may trace their roots to aversive childhood experiences, such as physical
Psychiatric Disorders

or sexual trauma. Despite their value in generating hypotheses concerning the causes of mental illness, psychodynamic theories have proven difficult to test.

Behavioral approaches, influenced by the work of John B. Watson (1878–1958), B. F. Skinner (1904–1990), Joseph Wolpe (1915–1997), and others, conceive of mental disorder as maladaptive learned habits. For behaviorists, atypical and disturbed behaviors are governed by the same learning processes as other behaviors. For example, behaviorists might attempt to explain a phobia of dogs in terms of an early unpleasant experience with a dog in conjunction with subsequent avoidance behavior. By avoiding dogs whenever they are within sight, the victim of a dog bite experiences short-term relief. Yet this person also forfeits the opportunity to learn that most dogs are not as dangerous as he or she fears.

Cognitive approaches, pioneered by Albert Ellis (b. 1913), Aaron Beck (b. 1921), and others, posit that psychological disorders derive from irrational patterns of thinking. Cognitive theorists emphasize that an individual’s interpretations of events, rather than events themselves, are the principal determinants of behavior. They regard unfounded beliefs about oneself, the world, and the future—such as the belief that “I must be perfect” or that “I must be liked by everyone to be a worthwhile person”—as risk factors for depression and other disorders.

Biological approaches focus on physiological factors, such as genetic influences, early damage to the central nervous system, and hormonal abnormalities, as predisposing factors in mental illness. There is compelling evidence from twin and adoption studies—which permit researchers to disentangle the roles of genes and environment—that genetic factors play a substantial role in a wide array of psychiatric disorders, including schizophrenia, mood disorders, and anxiety disorders. There is also preliminary but growing evidence that viral infections prior to birth may set the stage for subsequent schizophrenia.

The advent of sophisticated neuroimaging techniques such as PET (positive emission tomography) and fMRI (functional magnetic resonance imaging) has been a substantial boon to biological approaches, as these techniques have allowed researchers to discover which brain areas are underactive or overactive during certain tasks. For example, many individuals with schizophrenia exhibit decreased activity in their frontal lobes, which is consistent with the poor judgment, inadequate planning, and memory deficits often observed in this condition. The human genome project also promises to add to our understanding of the biological underpinnings of mental disorder, because it is permitting researchers to identify genes linked to specific psychological disorders.

Proponents of differing etiological models have often sorted themselves into highly partisan camps, separated as much by ideology as evidence. Yet, few if any of these etiological approaches are mutually exclusive. Moreover, most researchers and theorists agree that the causes of mental disorders are likely to be multifactorial, that is, produced by many variables rather than one. In some cases, these causal variables may interact. For example, several studies indicate that a genetic abnormality that affects serotonin, a chemical messenger in the brain, may combine with life stressors to trigger depression. As a consequence, the most fruitful approaches to understanding mental disorder will probably involve multidisciplinary collaborations among researchers from diverse theoretical perspectives.

PSYCHOANALYTIC THEORY

Founded by the Austrian neurologist and physician Sigmund Freud (1856–1939), psychoanalytic theory is a framework for understanding the impact of the unconscious on thoughts, feelings, and behavior. Freud posited that most of what motivates individuals lies outside of their immediate awareness. Borne out of Freud’s treatment of patients with neurological disorders, psychoanalytic theory describes both normal and abnormal human experience and emphasizes the lasting impact of early childhood events on adult personality and psychological development. Psychoanalysis, the clinical application of Freud’s theory, is a tool that explores the unconscious mind in order to relieve painful emotional symptoms and increase self-awareness. Psychoanalysis is the forerunner of most forms of modern psychotherapeutic techniques. To this day, psychoanalytic theory and the practice of psychoanalysis continue to evolve in ways that support, discard, and expand some of Freud’s original principles.

At the heart of Freud’s ideas was his seminal work The Interpretation of Dreams (1900), which describes dreams as unconscious wish fulfillments. Freud contended that there are core sexual and aggressive wishes that the conscious mind finds unacceptable and represses. These wishes are symbolically expressed in dreams. The surface details and narrative structure of the dream—what we remember—are referred to as the manifest content. The latent content of the dream represents its unconscious hidden meaning and can only be discovered through the process of interpretation.

Freud described other ways in which the unconscious is revealed in everyday life. For example, what Freud called a parapraxis, known today as a “Freudian slip” or “slip of the tongue,” is popularly understood to describe the occurrence of an unconscious wish “accidentally” being revealed in an individual’s speech or writing. For instance, a man who calls his wife “mom” may unconsciously reveal repressed thoughts or feelings that he has about either woman. Freud also argued that jokes can be derivative expressions of unconscious sexual or aggressive feelings disguised as humor.

Freud’s explication of dreams and the unconscious led him to develop a more comprehensive theory of the mind. His topographical model posited conscious, unconscious, and preconscious parts of the mind. The unconscious contains all that is outside of immediate awareness, whereas the conscious contains those parts of which individuals are immediately aware. Information that is not in immediate awareness but is easily retrievable is called preconscious. Freud used the analogy of an iceberg to describe this model: Only a small tip of a much larger iceberg is visible above water, much like only a small fraction of the mind is conscious. Most of the mind lies in the unconscious, below the level of awareness.

Complementing the topographical model, Freud also proposed a structural model of the mind that includes three parts: id, ego, and superego. The id is unconscious and active at birth, and encompasses all of the instinctual and bodily wishes. It operates according to the pleasure principle, which has as its sole goal the immediate gratification of all urges. The ego operates mostly out of the reality principle, which accounts for reality factors and social norms that prohibit instinctual urges from being immediately gratified. The ego helps to regulate the frustration from ungratified id drives. The superego is the moral part of the mind that represents an individual’s internalized sense of parental and societal values. Freud compared the conflict between the id and the ego to that between an unruly horse and its rider; the rider (ego) has to direct the unbridled energy of the horse (id) in a way that is neither too permitting nor too restrictive. These conflicts are at the heart of both classic and modern psychoanalytic theories’ understanding of symptoms, psychopathology, and defense mechanisms.

When unacceptable and unconscious id drives approach conscious awareness, a sense of danger and anxiety develops. Defense mechanisms are employed by the ego to defend against this anxiety. In a compromise formation, the ego attempts to express these id impulses in socially appropriate ways while accounting for the moral and societal values of the superego; there is a compromise between the original wish and the anxiety against the wish. Some examples of defense mechanisms are projection, displacement, reaction formation, and sublimation.

Projection occurs when an individual’s own unacceptable impulses are attributed to another person. The
Psychoanalytic theory encompasses views on human development and personality. According to Freud’s theory there are five stages of psychosexual development that children must negotiate. At each stage id energies, called libido, are focused on various parts of the body called erogenous zones. The stages are: oral, anal, phallic, latent, and genital. During each stage a child must negotiate fulfilling those pleasures in the context of growing social rules and norms. The pleasure area during the oral phase is the mouth, and actions such as sucking, teething, and biting are prominent. During the anal phase children must reconcile the pleasures of retaining and eliminating feces (and urine) and the socially imposed responsibility of toilet training. During the phallic phase bodily pleasures are obtained from self-stimulation of the genitals. It is during this phase that the challenge of the Oedipal complex is confronted. Fond of antiquity and the classics, Freud named this complex to invoke the themes of Sophocles’s Greek tragedy Oedipus Rex, a tragedy in which the character Oedipus unknowingly kills his father and marries his mother. Freud argued that in this complex, children feel repressed sexual attraction towards the parent of the opposite sex and aggressive hatred of the same-sex parent. During the next phase, the latency phase, libidinal instincts are repressed, only to reemerge at the start of puberty and the genital phase. At this time the focus is on genital pleasures with another person, leading toward the development of adult sexuality. When individuals have difficulty resolving the conflicts that each particular stage presents, they may become fixated, which affects adult personality.

These stages are important ideas in the history of psychoanalytic theory, but they are not distinct and precise developmental events. Rather, they are theoretical conceptualizations of some of the important challenges of psychological maturation. Nonetheless, they live on in modern parlance. Someone who is “orally fixated,” for example, may have been overly indulged during the oral phase of psychosexual development and later, as an adult, develop an oral symptom such as excessive drinking or cigarette smoking. An adult described as “anal” may be excessively concerned with orderliness, timeliness, and control, much as a toddler in the anal phase must negotiate the pleasures and challenges of bowel control.

Encompassed in psychoanalytic theory of all types are the ideas of cure and personal growth. Psychoanalysis represents the clinical application of psychoanalytic theory to the issues of psychopathology, neurosis, psychosis, and dysfunctional patterns of living. It is an intense form of psychological treatment that involves four to five sessions per week with a trained psychoanalyst (usually a psychiatrist, psychologist, or social worker) and lasts several years. Patients lie on a couch and are asked to speak as freely as they can about whatever comes to their minds, a process called free association. As with dream interpretation, the theory holds that free associations, no matter how irrelevant, obscure, or trivial they may seem, exhibit an internal logic that, through the process of interpretation, reveals conflicts of the unconscious that can be worked through to bring about symptom relief. Integral to this intense form of treatment is the development of transference, which occurs when a patient unconsciously transfers onto the psychoanalyst the thoughts, feelings, and conflicts that they have toward early caregivers. Working through the transferred conflicts in the unique interpersonal relationship with the psychoanalyst is a key component of the psychoanalytic theory of cure. Psychoanalytically informed psychotherapy, though similar in guiding principles, differs from psychoanalysis in that an analytic couch is not typically used, sessions are less frequent, and transference issues, though present, are not as fully integrated in the curative process.

As a prolific theorist, writer, and practitioner, Freud had many followers, some of whom broke ranks with aspects of his theory. Carl Gustav Jung (1875–1968), for example, was the heir apparent to the psychoanalytic movement until theoretical differences ended his professional relationship with Freud. Jung emphasized religion, archetypes, and what he called the collective unconscious, a culturally shared set of unconscious symbols. Alfred Adler’s (1870–1937) emphasis on individual striving for superiority and Karen Horney’s (1885–1962) integration
of feministic views of psychological development and functioning—something Freud is often criticized for ignoring—represent some of the earliest expansions of psychoanalytic theory.

Modern additions to psychoanalytic theory, such as object-relations theory, move away from strict drive- and conflict-motivated models to more relational and interpersonal ones. That is, interpersonal relationships, in addition to internal bodily drives and instincts, play an increasingly important role in individuals' conscious and unconscious notions of self and other. As such, these issues are often played out in rich and meaningful ways in psychoanalytic treatment, which most modern psychoanalytic practitioners view as inherently more relational than Freud's original conception.

The ever-evolving system of psychoanalytic theory that exists today is arguably one of the most far-reaching and pervasive theories of the last one hundred years. One can hardly escape the influence of Freud's unique system of thought. As a theory of symbolic and hidden meanings, psychoanalytic theory is often applied to the critical understanding of literature, poetry, cinema, and the visual arts. Anthropologists have used psychoanalytic ideas to explore and understand the relationship between individuals and their cultures. Modern neuroscience has even paved the way for the emerging field of neuropsychoanalysis, which aims to integrate psychoanalytic ideas with physically observable brain structures, neural pathways, and brain chemistry. Psychoanalytic theory has often been criticized as being the unscientific, dogmatic, chauvinistic, illogical, and narcissistically insular theory of one man, Freud. Fair though aspects of these criticisms may be, the psychoanalytic theory of today offers a comprehensive and cogent account of the human condition.

PSYCHOLINGUISTICS

Psycholinguistics studies the way in which operations of the mind make language possible. It is a cross-disciplinary field, drawing upon ideas and findings from areas such as cognitive psychology, theoretical linguistics, phonetics, neurology, discourse analysis, computer science, semantics, and education. It is especially indebted to the first of these, which provides many of its basic tenets and its research methods.

Specifically, the field explores the cognitive processes that underlie the use, storage, and acquisition of language. Affective and contextual factors are a concern only as far as they impact upon performance. Although psycholinguists recognize that language users are individuals possessing different linguistic repertoires, their main goal is to identify general patterns of behavior across users. Those patterns might reflect the capabilities and biases of the human brain or the processing requirements of the language under investigation.

Psycholinguistics has a relatively recent history. It did not come into its own as a subject until the early 1960s, when behaviorist approaches to the study of the mind lost favor. However, interest in related topics can be traced back to eighteenth-century diaries recording the language development of children, to nineteenth-century research on the location of language in the brain, to the introspective methods of Wilhelm Wundt's psychology laboratory (established 1879), and to Francis Galton's work on word associations.

LANGUAGE PROCESSING

Those who work in the field of language processing seek to identify the processes, often highly automatic, that underlie the two productive skills (speaking and writing) and the two receptive ones (listening and reading). Starting with the generation of ideas, accounts of language production allow for macro-planning at discourse level and local micro-planning in relation to the utterance...
about to be produced. The resulting plan is given linguistic form, which is stored in what is termed a mental buffer while the utterance is being produced.

Accounts of language reception recognize two stages. In decoding, the user identifies units of language within the input and builds smaller ones into larger. Current models represent the listener or reader as seeking potential matches at many different levels of representation (sound, letter, syllable, word) as well as relying on external cues provided by sources such as world knowledge or speaker knowledge. There were early suggestions that skilled readers and listeners spared themselves decoding effort by relying upon contextual cues. However, the key to skilled performance has been shown to lie in efficient decoding, which releases memory capacity and enables the reader or listener to give adequate attention to higher-level meaning.

Meaning construction is heavily dependent upon a process of interpretation. It requires the reader or listener to expand on the literal significance of the input by adding in what the writer or speaker appears to have left unexpressed. The user also decides on the relative importance of the new information, adds it to the meaning representation built up so far in the discourse, and checks for consistency.

Some language processing research relies upon observational data or upon introspective methods such as verbal report. However, the most favored approach is experimental. Importance is accorded to methods that tap in to processes on line, in other words, as they are occurring. There is a preference for parametric data in the form of, for example, the reaction times involved in carrying out a small-scale task such as distinguishing actual words from non-words.

**LANGUAGE STORAGE**

A long-term area of interest has been the way in which vocabulary is stored in the language user’s mental lexicon. A word’s lexical entry specifies its spoken and written forms, its word class, its senses, and the way it participates in larger linguistic structures. There is uncertainty as to whether word-forming prefixes and suffixes such as *un-* or *-less* have their own entries. Current theory represents entries as interconnected within the mind of a user, with much stronger connections between those that frequently co-occur.

More recently, interest in storage has been extended to the ways in which sounds and grammar are represented in the mind. In conventional accounts, it tends to be assumed that sounds are stored as templates or prototypes against which variations can be matched, while grammar takes the form of abstract, internalized rules. However, growing evidence of the enormous storage capacity of the mind suggests that language users may retain precise records of the many utterances they encounter throughout their lives. Their ability to recognize sounds, words, and even patterns of grammar consequently derives not from generalizations but from millions of accumulated examples. On this analysis, the frequency with which strings of sounds and words are encountered is an important factor in the ease with which an individual retrieves them when they are needed. The premise is supported by evidence from computer modeling on connectionist principles, which has shown (so far in a limited way) that it is possible for a program to acquire a set of grammatical rules and exceptions by dint of exposure to repeated examples.

**LANGUAGE ACQUISITION (OR DEVELOPMENTAL PSYCHOLINGUISTICS)**

Any discussion of how children acquire language is influenced by the long-running debate as to whether language is innate and genetically transmitted (a nativist view) or whether it is acquired wholly or mainly through exposure to the language of adult caregivers (an empiricist view). Early comments by the American linguist Noam Chomsky (b. 1928) about the poverty of the stimulus (the uninformative nature of the speech samples provided to the child) have been challenged by analyses of child directed speech (CDS). Many child language researchers therefore adopt a neutral position or propose that language may be partly innate.

Research in this area falls into two broad traditions. One is theory-driven and adopts the assumption that linguistic descriptions of grammar correspond to actual mental processes. Drawing especially on Chomskyan accounts, this line of enquiry seeks evidence in children’s speech of universals of language, of common default values for certain features and of the adjustment of those values to match the target language.

A second branch is data-driven. It studies samples of child language, using the analytical tools provided by mainstream linguistics and discourse analysis. Researchers have formed conclusions about the way in which a child develops a phonological system, although the precise relationship between hearing and producing spoken words remains unclear. Vocabulary has been studied in relation to the words that are acquired earliest and to the rate at which the child’s knowledge increases. Especially important have been studies of how the child manages to construct conceptual categories such as *flower* or *bird* from discrete examples of the category. Studies of grammar have monitored the gradual increase in length of utterance and in the complexity of the syntax used and the concepts expressed.

The research method most favored in language acquisition studies consists of longitudinal observation based
upon diaries or recordings. One outcome has been the assembly of a large international corpus of child language known as the Child Language Data Exchange System, or CHILDES. Researchers sometimes employ interviews with children to elicit specific linguistic items. Experimental methods have also been devised that enable a researcher to track the shifts of attention of a prelinguistic infant and thus to assess the infant’s ability to discriminate between different signals.

A very different area of acquisition research investigates the way in which learners master a foreign language. Psycholinguistic theory provides a framework for studying both the cognitive processes that lead to expertise in the target language and the additional cognitive demands imposed upon the second language (L2) user by unfamiliar phonology, lexis, and syntax. The concepts of attention, working memory, and automaticity have proved especially useful; and an understanding of L2 fluency has been enhanced by first-language evidence of how speech is assembled.

TECHNOLOGICAL ADVANCES

In recent years, all these areas of psycholinguistics have been assisted by technological advances, especially the advent of brain imaging equipment. Researchers can now monitor brain activity while a subject is undertaking a language processing task; the purpose being to discover which parts of the brain are engaged and at which stages. They can identify where different types of linguistic information are located within the brain. They can even track the processing taking place in the brains of prelinguistic children.

Recent neurolinguistic findings build upon a long tradition of research on language in the brain, going back to the nineteenth century. It was assumed then that language was lateralized to the left hemisphere for most language users and stored in two small areas, named after the researchers Paul Broca (1824–1880) and Carl Wernicke (1848–1905). However, modern technology has demonstrated that the right hemisphere also plays its part, handling larger-scale constructs such as intonation and discourse structure. It has also shown that language is widely distributed throughout the brain, relying upon massive neural connections for rapid transmission.

Loosely associated with the study of language in the brain are a number of other areas of enquiry. One explores the question of whether language is a form of communication peculiar to human beings; another, the question of how language evolved. Both consider the possibility that language owes its existence to the unique configuration of the human brain in addition to the evolution of the human vocal apparatus.

A final area worth noting is the contribution that psycholinguistics makes to an understanding of language impairment—both developmental impairment (manifested from infancy) and impairment that is acquired as the result of accident or illness. Psycholinguists concern themselves with the processes that contribute to dyslexia and dysgraphia, with aphasic symptoms produced by strokes, and with disorders of speech. Besides contributing to the work of clinicians, this research helps to shed contrasting light on normal language processing. Similarly, work on the relationship between language and other cognitive skills in conditions such as Down syndrome or autism provides insights into whether language is part of general cognition or develops independently of it.

PSYCHOLOGICAL CAPITAL

Conventional microeconomics assumes that individuals seek to maximize their happiness, often called utility, by consuming goods and services while being constrained by
their earnings. Tibor Scitovsky (1976) in his seminal work on consumer behavior suggested that psychological factors such as arousal, status, and sense of control over life events may influence happiness. In addition, Art Goldsmith, Jonathan Veum, and William Darity Jr. (1997b) assert that psychological elements affect workplace performance and, hence, earnings. Thus, psychological factors must be accounted for to attain a rich understanding of consumer behavior. Behavioral economics is the subfield of economics that integrates insights from economics and psychology into the study of economic and social behavior. “Psychological capital” refers to the collection of values, norms, perceptions, cognitive elements, and affective or emotional factors embedded in a person that can be expected to influence happiness and earnings. This essay provides an overview of how the concept of psychological capital has been integrated into social science research.

PSYCHOLOGICAL CAPITAL, HAPPINESS, AND EARNINGS
The roots of behavioral economics, and hence the importance of psychological capital, can be found in the discovery by economists that economic motives are often at odds with actions and that in many instances psychological elements appear to shape behavior. For instance, conventional economists adopt the assumption that individuals are rational decision makers who compare the additional benefits and costs of an action and engage in those activities offering a net gain. This perspective, however, is difficult to square with many commonly observed behaviors including customers tipping at a restaurant they will never again frequent because it is so far from their home. Psychologists explain this behavior as evidence that actions are guided by values, such as fairness, and cultural norms learned through socialization. There is also reason to believe that perceptions regarding safety and economic security are important determinants of happiness. Joblessness, especially unemployment, creates a sense of economic vulnerability. Goldsmith, Veum, and Darity (1997a) draw a connection from unemployment to poorer psychological well-being in several distinct but interrelated ways: as a consequence of lower self-esteem; as a result of a feeling that life is not under one’s control, leading to helplessness and depression; and as a loss of the social byproducts of participation in a work environment.

Psychological elements are expected to affect a person’s wage, which in turn influences his or her level of consumption and happiness. A standard argument in economics is that a person’s wage is tied to his or her workplace performance or productivity, which is largely governed by his or her level of skills, called human capital. Of course, effort on the job is also expected to influence productivity and wages. Carl Shapiro and Joseph Stiglitz reported in 1984 that economists claim that workplace effort is promoted by fear of joblessness or, according to George Akerlof in 1982, to reflect gratitude for favorable treatment by the firm. Expectancy theory is the most widely accepted and empirically supported theory of motivation or effort among psychologists. According to expectancy theory the strength of a person’s motivation depends on the extent to which he or she believes that exertion, performance, and reward are linked tightly. Attribution theorists have proposed that an aspect of personality—locus of control—governs a person’s perception of the strength of the connection between exertion, performance, and reward. Julian Rotter in 1966 classified individuals who believe they are masters of their own fate, and hence bear personal responsibility for what happens to them, as internalizers. Externalizers are those who believe they have little, if any, influence on the events that influence their lives. Expectancy theory predicts that a person with a more internal locus of control will be more motivated than a comparable individual whose locus of control is external.

MEASURING PSYCHOLOGICAL CAPITAL
Psychological capital is a broad term used to encompass various features of an individual’s mind-set and personality, including motivation and emotional wellbeing. The convention in psychology is to use a battery of questions, called an inventory, to obtain a scale that gauges the psychological construct to be measured, such as motivation—locus of control—or self-esteem. Morris Rosenberg developed a survey instrument in 1965 to measure self-esteem because opinions about “self” are virtually the most treasured of our opinions and a crucial aspect of personality. He conceives of self-esteem as multidimensional, comprising notions of worth, goodness, health, appearance, skills, and social competence. Rosenberg uses a series of questions, each answered on a two point (0,1) basis. His measure of self-esteem may range in value from 0–6, with a higher value representing a greater level of self-esteem. Herb Lefcourt used a similar methodology in 1982 to measure locus of control, with larger values reflecting a more internal orientation, and hence a higher level of motivation.

Many economists are skeptical that elements of a person’s psychological capital, such as locus of control, can be measured accurately by scales constructed from self-reported evaluations collected in the form of responses to survey questions. Their concerns are twofold. First, that it is difficult to compare responses across individuals because their replies are not anchored to a common baseline. Consider a question aimed at assessing a person’s mental health that asks how often they have feelings of
Psychological Defense

anxiety, with response options including; 1 equating to never, 2 for occasionally, 3 representing often, and 4 meaning all of the time. Two different persons who have similar bouts of exposure to depression may answer this question differently, one reporting occasionally and the other often, resulting in misclassification error because their frame of reference is different—there is no common baseline. To reduce this problem investigators transform responses to a two-point scale such as never versus not never, which reduces misclassification error.

The second concern is that subjective responses may differ widely from objective evaluations. A person may report feeling anxious while a professional evaluation of the individual conducted by a physician or clinical psychologist may lead them to conclude that the person is not suffering from anxiety. Research by Anne Case, however, offers evidence that a person’s subjective responses to health questions about his or her children are virtually identical to independent assessments conducted by a physician. Thus, social scientists now conduct empirical studies of the link between psychological capital and economic outcomes. For instance, as reported by Goldsmith, Veum, and Darity in 2000, they find that persons who are more internal in their outlook—those more motivated—earn higher wages, and that unemployment leads to lower self-esteem and a more external perspective (1997a). The mental health consequences of adverse developments, however, will be less severe for persons with an external outlook because they do not blame themselves for the situation. Thus, high status individuals with an internal locus of control are particularly vulnerable in terms of emotional well-being to negative occurrences that arise at the workplace or in the family. Minorities often hold an external locus of control both as a result of past discrimination and as a defense mechanism to avoid self blame for undesirable outcomes that are beyond their control. Thus, members of minority groups may experience less harm to their mental health due to adverse social and economic developments.

PSYCHOLOGY

The term psychology has been used to refer to the study of the soul, consciousness, behavior, the mind, or the brain, depending on the era and cultural context investigated. In the nineteenth century German philosopher-psychologist Friedrich Eduard Beneke (1798–1854) defined his new psychology as the natural science of inner experience and suggested that the subject matter of psychology was what one finds in oneself. His countryman Wilhelm Wundt (1832–1920), who is often considered one of the central figures in the creation of modern psychology, defined the subject matter of psychology as the total content of experience in its immediate character. William James (1842–1910), one of the pioneers of American psychology, defined psychology as the science of mental life, both of its phenomena and of its conditions.

In a 1989 study, Tracy B. Henley and his colleagues showed that in the first third of the twentieth century psychology was defined the majority of the time as including concepts of mind, consciousness, or mental activity. Between 1930 and 1969, the prime time of behaviorism, these terms were barely mentioned in North American psychology, although with the coming of the cognitive rev-
olution they became widely used again. Use of the term behavior increased throughout the twentieth century, with later definitions including both behavior and mental activity. Definitions of psychology reflect the dominant research programs in a particular context.

PSYCHOLOGICAL TOPICS
Psychology did not exist as an independent discipline before the nineteenth century, although psychological topics were studied long before then. The study of the soul ( psyche) goes back to Greek philosopher Aristotle (384–322 BCE) who wrote a pioneering work entitled, in Latin, De anima (On the soul). Aristotle discussed the five senses as well as perception, thinking, and imagination. He also discussed memory and dreaming. He did not study intelligence quotient (IQ), motivation, or prejudice, however, which are all later psychological constructions.

In the eighteenth century German philosopher and mathematician Christian Wolff (1679–1754) divided the study of the soul into two parts: rational psychology and empirical psychology. Rational psychology depicted what the human soul was capable of. He discussed the soul’s substantiability, simplicity, immateriality, immortality, as well as the mind-body problem, and provided logical proofs that the soul was immaterial. Empirical psychology aimed to identify psychological principles on the basis of concrete experiences of what actually happened in the human soul. Empirical referred to something that could be determined through experiences rather than reason. Wolff’s empirical psychology addressed the ability of the soul to know and to desire, the interaction of the soul and the body, and the faculties of the soul. Psychology concerned the study of the soul until the mid-nineteenth century, when German philosopher Friedrich Albert Lange (1828–1875) proclaimed a psychology without a soul.

Present-day psychology covers a wide range of topics such as biological bases of behavior, sensation, perception, memory, cognition, emotion, motivation, learning, language, dreaming, social interaction, prejudice, development, aging, intelligence, personality, stress, psychopathology, and psychotherapy. In psychology each concept is subdivided and studied in its parts: For example, memory is subdivided into short-term memory, long-term memory, working memory, explicit memory, and implicit memory, among others. Memory can be researched from a developmental, social, or biological perspective, each of which provides a variety of theoretical frameworks.

PSYCHOLOGY AS A DISCIPLINE
In the sixteenth century the word psychologia (psychology) first appeared in a book title, although some research does indicate earlier usage of the term. In 1590 Rudolf Goclenius (1547–1628), a German professor of physics, mathematics, logic, and ethics used the term.

Some historians suggest that the acceptance of psychology as an institution of research and teaching at universities first occurred during the first half of the nineteenth century during a period of transformation for German universities. With the establishment of state-funded and state-controlled classical high schools, professors of philosophy were asked to teach courses on psychology and pedagogy for classical high school teachers-in-training. Because psychology was understood as the scientific basis for pedagogy, teacher candidates were required to take exams in the discipline of psychology. Horst Gundlach (2004) offers 1824, the year in which Prussia established psychology as an examinable discipline at its universities, as the origin of the discipline of psychology. Most books on the history of psychology, however, list its inception from 1879, the year in which Wundt began to conduct psychological experiments in his new psychological laboratory at Leipzig, Germany. From a critical perspective it is difficult to attribute the birth of a discipline to a single event. The institutionalization of psychology—the establishment of an academic discipline that followed university rules—occurred at different times in different geographical or national contexts.

PSYCHOLOGY AS A PROFESSION
Psychology as a profession or an expert occupation became a reality in the twentieth century. The professionalization of psychology can be linked to the development of other institutions in European and North American culture. The transformation of the legal system required experts, for example, regarding the validity of testimony and the reliability of memory; the health system needed experts in dealing with the mental health problems of patients; the prison system sought professionals who could provide information on the progress of rehabilitation and the likelihood of re-offending; the school system needed expertise in order to determine which children would need special education; and industry and corporations needed experts on personnel selection, the improvement of productivity, and advertising. In all of these applied fields psychologists emerged and claimed scientific knowledge.

In addition, public demand for psychological expertise increased; for example, regarding the parenting of children, people sought advice on the adequate amount of emotional contact, sensory stimulation, potty training, masturbation, and the appropriate extent of parental control at different ages. The search for expertise on how to have fulfilling romantic relationships, to be successful, and even live life led to the birth of pop psychology. Prominent examples of pop psychologists include former...
academic John B. Watson (1878–1958), whose book *Psychological Care of Infant and Child* (1928) contained historically contingent ideas such as that one should never hug or kiss a child, and Dr. Phil McGraw, whose media-magnified psychological activities are largely rejected by academic psychologists. There were a number of troubling manifestations of the professionalization of psychology as well: German psychology expanded in the context of the militarization of the *fatherland* at the beginning of the twentieth century; and U.S. psychologists, using IQ tests, labeled populations from Eastern and Southern Europe and non-European races mentally inferior during the great immigrations of the same time period.

**PSYCHOLOGY’S RISE**

According to Steven Ward, psychology’s integration with other institutions has made it a uniquely successful field. Psychology flourished in the twentieth century in terms of its intellectual and social expansion. Psychology is one of the most popular undergraduate majors in North America and many European countries. The American Psychological Association (APA), the largest association of psychologists worldwide, has 150,000 members. The APA has more than fifty divisions that cover traditional experimental, social, developmental, or clinical psychology; the psychological study of lesbian, gay, and bisexual issues; peace psychology; and the advancement of pharmacotherapy, among many other diverse topics.

There are several thousand journals dedicated to psychology, and the APA’s *Publication Manual* (2001), a style guide, has been adopted by most psychologists and by professionals in other disciplines as well. As a profession psychology pervades popular consciousness in the twenty-first century. The increasing global dominance of American psychology after 1945 reflects the economic power of the United States. But psychology did not only succeed as an institution; it also thrived in the *psychologization* of human life. The public and many expert cultures explain human and social events in psychological terms: Individual decisions, the arts, political crises, economic problems, history, and terrorism are all explained with the help of psychological categories.

**CONTROVERSIES IN PSYCHOLOGY**

The importance of psychology as a scientific discipline and in everyday life is clear. However controversies regarding basic precepts continue among psychologists.

The Dualism of Psychology Psychology can comprise understanding or explaining psychological objects and events. For example, one can explain the physiological mechanisms of memory or one can understand the specific content of a person’s memory that is formed within meaningful life experiences. Psychologists with a *natural-scientific* orientation emphasize the explanation, prediction, and control of behavior or cognition, while psychologists with a *human-scientific* perspective focus on thinking, feeling, and willing based on the assumption that reflection, intention, and action are meaningful processes. German philosopher Wilhelm Dilthey (1833–1911) provided a systematic foundation for two types of psychology when he divided the discipline into *descriptive* (human-scientific) and *analytical* explanatory (natural-scientific) parts. He argued that psychology’s subject matter was human experience and thus its method must be understanding. German experimental psychologist Hermann Ebbinghaus (1850–1909) endorsed psychology as a natural science that did not need the method of understanding and should rely on natural-scientific explanation and experimental methods. Wundt, who many see as the father of German experimental psychology, divided the science into an experimental branch that focused on precise analysis of the basic processes of consciousness, and an observational *Völkerpsychologie* (cultural psychology) that covered complex psychological processes that accompany the development of human communities and mental products in the context of values, customs, and language.

In the North American tradition Gordon Allport observed an increasing *nomothetic*, natural-scientific commitment of psychology, but he petitioned for the inclusion of an *idiographic* approach in scientific psychology. Human-scientific approaches (hermeneutic, existential, humanistic psychologies) generally have been marginalized since the twentieth century, although they have never been totally abandoned, especially in clinical contexts. The impact of the natural-scientific approach was so powerful that even Sigmund Freud considered his method of psychoanalysis to be natural-scientific. The dualism of psychology is surfacing again in discussions surrounding *quantitative* versus *qualitative* methods, with the latter gaining more acceptance in the early twenty-first century.

**Unification** Dualism is one facet in an ongoing discourse regarding unification. Since the end of the nineteenth century, theoretical psychologists and later Russian psychologist Lev Semyonovich Vygotsky (1896–1934) have critiqued the missing unity of psychology. In the first half of the twentieth century the focus was on the unification of large research programs such as psychoanalysis, behaviorism, Gestalt psychology, and structuralism, and later unification was demanded regarding the multiplicity of theories, approaches, and empirical results that were often contradictory. Psychology as it exists in the early-twenty-first century is so diverse in its conceptual and theoretical positions and so fragmented in its identity that multiple psychologies rather than a unitary psychology have prevailed.
Solutions to the unification problem in the past have largely been based on a conceptual reductionism in promoting a single program such as behaviorism. Some have called for unifying theories of unification before any unification of the discipline could succeed. Proponents of unification demand unification for theoretical reasons. For example, the increasing demand for interdisciplinary work must remain fragmented if it is not clear what the discipline of psychology stands for. Opponents of unification suggest that the lack of unity makes psychology an extremely adaptive discipline that is able to work with other fields in academic and applied settings. The factual lack of theoretical unity has led to the phenomenon that mainstream psychology identifies itself by the commitment to a specific methodology, namely an experimental-statistical point of view.

**Dichotomies** Psychology throughout its history has struggled with conceptualizing the relationship between society and the individual, nature and nurture, and mind and body. The lack of an adequate conceptualization of the individual and society has led to criticisms that psychology is too individualistic in its theories and practices. For example, a person’s psychological distress regarding homelessness cannot solely be explained, understood, and solved on an individual level. Even social psychology, which by definition should take the social context into account, does not provide ecological relevance because many studies use undergraduate students in laboratories as subjects. Klaus Holzkamp (1972) argues that in the real world there are many more variables that influence behavior and cannot be included in their complexity in an experiment.

The mind-body problem has been addressed in behaviorism in a reductionist way by denying or neglecting the reality of a mind. Neuropsychological researchers have developed more sophisticated theories since the late twentieth century. The largest political impact derives from an inadequate conceptualization of the nature-nurture debate. This dichotomy is most prominent in IQ controversies but also surrounds the heritability of pathologies, personality, and other psychological characteristics. The lack of an adequate understanding of nature-nurture has led psychologists to make premature judgments about alleged inborn intelligence. The heritability of intelligence received widespread public attention in the context of British educational psychologist Cyril Burt’s (1883–1971) fraudulent data on twins and in connection with the issue of “race.” As Stephen Jay Gould and others have pointed out many interpretations were unsupported by data but these interpretations were presented as factual knowledge. Many of the premature conclusions should be labeled *epistemological violence* (Teo 2005).

**Natural Kinds versus Social Kinds** More recently there has been a debate regarding whether psychological concepts are *natural kinds* or *social kinds*. Kurt Danziger (1997) suggests that many psychological concepts are social constructions that have become social reality. This idea has had an impact on research and practice and means that psychological concepts are bound to culture not to nature. Thus American or European psychology, indigenous psychologies themselves, cannot be exported straightforwardly to another cultural context. Many psychologists are often unaware that in believing their concepts can be used globally, they display misplaced ethnocentrism.

**Professionalization** The professionalization of psychology itself is a debated topic in academia. There have always been proponents and opponents, and this struggle has continued into the twenty-first century. For example, in the United States an American Psychological Society was founded in 1988 as a response to APA, which was perceived as catering to the interests of applied psychologists but not academics. One of the recent topics discussed in the context of the profession are prescription privileges for psychologists in some U.S. states. This topic is significant because it connotes a shift from a psychological to a medical model of mental illness. From the perspective of health insurers, allowing psychologists to prescribe drugs means cost reduction. However, giving such rights to psychologists challenges a long-standing privilege reserved to medical doctors, with probable economic consequences for that profession.

PSYCHOLOGY, AGENCY IN

The concept of agency as a psychological dimension refers to the process of behaving with intentionality. Human beings exercise agency when they intentionally influence their own functioning, environments, life circumstances, and destiny. To posit that human beings have agency is to contend that they are self-organizing, proactive, self-regulating, and self-reflecting rather than reactively shaped by environmental forces or driven by concealed inner impulses. This is not to say that people always behave agentially. A driver who inadvertently runs a stop sign would not be considered the agent of that event because he did not intend to commit the infraction. An intention is a mental representation of a future course of action to be performed. It represents a proactive commitment to act.

Human agency has four core properties. The first is intentionality. People create and engage plans and strategies with which they realize their predetermined intentions to act in a certain manner. The second property is forethought, which addresses the temporal dimension of human agency. People make plans, set goals, and anticipate the likely outcomes of their prospective actions. To set plans in motion so as to bring about the desired outcomes, people must self-regulate their thinking and behavior. Thus, the third property of human agency is self-reactiveness, a process through which individuals not only make plans and choices but also construct the appropriate courses of action and regulate their execution. Because actions must be examined in order to be corrected, the fourth agentic property is self-reflectiveness. Through proactive self-awareness, people can reflect on their capabilities, the soundness of their thoughts and actions, and the meaning of their pursuits. As a consequence, they can make needed adjustments.

In addition to possessing four properties, agency operates through three modes: individual, proxy, and collective. When agency is exercised individually, one brings one’s own personal influence to bear on one’s own functioning and on the environmental events that comprise one’s life. When people cannot exercise their personal influence, however, they must seek their well-being and obtain the outcomes they desire through the exercise of proxy agency. In this mode, people appeal to others who can secure these benefits for them. Thus, children turn to parents, students to teachers, and citizens to elected officials. Finally, people must often work together to obtain the things they need. Thus, they must pool their knowledge, skills, and resources, form alliances to advance common interests, and work collectively to obtain those things that they cannot obtain on their own.

To exercise human agency, people must believe in their capability to attain given ends. These self-efficacy

Thomas Teo

PSYCHOLOGY, ADOLESCENT

SEE Adolescent Psychology.
beliefs are the foundation of human motivation, well-being, and accomplishment. Whatever other factors serve as guides and motivators, they are rooted in the core belief that one has the power to effect changes by one’s actions, that one’s locus of control is internal rather than external. This is because unless people believe that their actions can produce the outcomes they desire, they have little incentive to act or to persevere in the face of difficulties.

PSYCHOMETRICS

Psychometrics literally means “psychological measurement.” It is the methodology that deals with designs, administrations, and interpretations of measurement on individuals’ constructs such as abilities, attitudes, personality, knowledge, quality of life, and so on. There are several major components in psychometric theory, including classical test theory, item response theory, factor analysis, structure equation modeling, and statistical methods and computing. A psychometrician is an expert who practices psychometrics. He or she usually holds a postgraduate degree in either educational measurement or quantitative psychology.

CLASSICAL TEST THEORY

Reliability is a major concern for any kind of measurement, which copes with issues in measurement consistency. Classical test theory (CTT) views the score of an individual as a random variable $X$ that can be decomposed by a fixed true score $T$ plus an error: $X = T + E$, where the expected value of $X$ is $T$, that is, $E[X] = T$ and $E[E] = 0$. Moreover, for a given population, $\sigma^2 = \sigma_T^2 + \sigma_E^2$. If $\sigma_E = 0$, then the measurement $X$ is perfectly reliable. Thus, the reliability of a test, often denoted as $\rho_{XX}$, can be defined as

$$\rho_{XX} = \frac{\sigma_T^2}{\sigma_X^2} = \frac{\sigma_T^2}{\sigma_T^2 + \sigma_E^2}.$$

According to the above, $\sigma_E = \sigma_X \sqrt{1 - \rho_{XX}}$. Therefore, for a student who received score $X$, a 68 percent confidence interval for his or her true score is $X \pm 1(\sigma_X)$. Adequately quantifying indices to measure reliability is at the core of CTT. Let $\rho_{XX}$ be the correlation coefficient between $X$ and $T$. It can be proved $\rho_{XX}^2 = \rho_{XX}$, where $\rho_{XX}$ is the Pearson correlation between $X$ and $T$. In statistics $\rho_{XX}$ is interpreted as the proportion of variation in $T$ that is related to the variation in $X$. Thus, the larger the value of $\rho_{XX}$, the more reliable the measurement. Because $T$ is unobservable, methods were proposed to estimate $\rho_{XX}$. For example, if two parallel forms of a test are administered simultaneously to the same population, it can be proved $\rho_{XX} = \rho_{XT}^2$, where $X$ and $X'$ are scores of the two tests and $\rho_{XX}$ is the correlation. This implies that reliability can be estimated from two parallel tests. When there is only one single test available, the correlation between its odd and even items, say $\rho_{YY}$, measures the internal consistency between the half-tests and is called the “split-half reliability coefficient.” According to the Spearman-Brown formula, the reliability for the entire test can be obtained from that in half-test:

$$\rho_{XX} = \frac{2\rho_{YY}}{1 + \rho_{YY}}.$$
In the early days of psychometric research, numerous methods were proposed to estimate reliability indices, including Cronbach’s coefficient-α, Kuder-Richardson’s KR-20, and so on.

Another important concept in psychometrics is validity, which concerns the purpose of measurement; a measure is valid if it measures what it purports to measure. A pivotal task in psychometric research is to search for adequate methods to assess all kinds of validities, such as content validity, criterion related validity, and construct validity. Though they all were created to gauge the correlation between a measure and its purpose, each one plays a unique role. Criterion related validity is used to demonstrate the accuracy of a measure with respect to a criterion that has been demonstrated to be valid. For example, a job-screening test was shown to be an accurate test for job performance. Let $X$ be the job-screening test score collected last year and $Y$ be the job-performance rating of this year, where $X$ can be called a predictor score and $Y$ is called a criterion score. A straightforward quantity to assess the validity by using $X$ to predict $Y$ is the Pearson correlation between $X$ and $Y$, $r_{XY}$. The larger the value of $r_{XY}$ is, the more valid it is to use test score $X$ to predict $Y$. $Y$ can be predicted by least-squares linear regression

$$
\hat{Y} = r_{XY} \frac{\sigma_Y}{\sigma_X} (X - \bar{X}) + \bar{Y},
$$

where $\hat{Y}$ is the predicted criterion score, $\bar{X}$ and $\bar{Y}$ are the sample means, and $\sigma_Y$ and $\sigma_X$ are sample standard deviations.

Construct validity is a relatively newly developed form of validity. It refers to the degree to which the measure associates the construct that it was designed to measure. According to Mary Allen and Wendy Yen (1979), establishing construct validity is an ongoing process that involves the verification of predictions made about the test scores. Suppose a new test is proposed to measure a construct; according to theory, male and female should perform similarly if they are all at the same construct level. This hypothesis needs to be tested. If the testing is supported by the data analysis, the construct validity is enhanced.

**FACTOR ANALYSIS**

Factor analysis (FA) is another important component in psychometric theory. It has been commonly used to examine the structure of correlations among a set of observed scores. These scores can be either subscores of a test or the scores of several different tests. When FA is conducted, tests that are influenced by the same factor are shown to have high factor loadings on such factor. By conducting FA, researchers can identify factors that explain a variety of results among subtests or different tests. For example, a potential research question could be “How many traits are these tests measuring?” There have been immense applications and generalizations, including both confirmatory factor analysis and exploratory factor analysis. FA was originally developed within psychometrics for studying human intelligence testing, but it has become a frequently used methodology in many areas of psychology, social sciences, business, economics, engineering, and biology.

**ITEM RESPONSE THEORY**

Item response theory (IRT) is a relatively new methodology in psychometric theory. It is also referred to as “latent trait theory.” In CTT the true score of an examinee, which can be interpreted as the examinee’s ability level, is test dependent. When the test is easy, the examinee tends to have high true score; when the test is difficult, the examinee tends to have lower true score. The difficulty level for either an item or a test is population dependent.

In order to overcome the shortcomings of CTT, IRT was created in an attempt to incorporate certain desirable features, such as examinee ability estimates, which are not test dependent, and item characteristics, which are not group dependent. IRT is based on certain fundamental assumptions: (1) For a dichotomously scored item, the performance of an examinee on the item can be predicted by knowing his or her latent trait (or set of latent traits); and (2) the relationship between examinees’ item performance and the required latent trait (or traits) to perform on the item can be described by a response function (see, e.g., Hambleton, Swaminathan and Rogers 1991). As for a polytomously scored item, a set of response functions are needed.

Different models were proposed. The most commonly used model for dichotomously scored items is a three-parameter logistic model. Let $X$ be the score for a randomly selected examinee on the $j$th item; $X = 1$ if the answer is correct and $X = 0$ if incorrect, and let $X = 1$ with probability $P(\theta)$ and $X = 0$ with probability $1 - P(\theta)$ where $P(\theta)$ denotes the probability of a correct response for a randomly chosen examinee of latent trait $\theta$; that is, $P(\theta) = P(X = 1|\theta)$, where $\theta$ is unknown and has the domain $(-\infty, \infty)$ or some subinterval on $(-\infty, \infty)$. When the three-parameter logistic model (3PL) is used, the probability becomes

$$
P_j(\theta) = c_j + (1 - c_j) \frac{1}{1 + e^{-a_j(\theta - b_j)}},
$$

where $a_j$ is the item discrimination parameter, $b_j$ is the difficulty parameter, $c_j$ is the guessing parameter.

Polytomous IRT modeling is another important application in IRT. Assume that the response of an examinee to the $j$-th item can be categorized into one of a set of $m + 1$ categories; that is,

$$
P_{jk}(\theta) \equiv \text{Prob}[X_j = u_k|\theta].$$
In other words,

\[ X_j = \begin{cases} u_{j0}, & \text{with probability } P_{j0}(\theta), \\ u_{j1}, & \text{with probability } P_{j0}(\theta), \\ \vdots & \vdots \\ u_{jm}, & \text{with probability } P_{jm}(\theta), \end{cases} \]

where \( \sum_{k=0}^{m} P_{jk}(\theta) = 1 \), and \( P_{jk}(\theta) \) is referred to as the item category response function. When the category sequence is an increasing order \( u_{j0} < u_{j1} < \ldots < u_{jm} \), the model is referred to as an “ordered polytomous model.” There are numerous IRT models, such as the graded response, partial credit, and nominal models.

Popular applications of IRT include latent trait estimation, item parameter calibration, modeling and detection of differential item functioning (DIF), linking and equating, and computerized adaptive testing.

**NEW DEVELOPMENTS IN PSYCHOMETRIC THEORY**

Perhaps one of the biggest challenges for psychometricians today is how to keep abreast of the rapid developments in technology. Computerized Adaptive Testing (CAT) and Internet-Based Testing (IBT) are undergoing rapid growth. Although the implementation of new technologies has led to many advantages, such as new question formats, new types of skills that can be measured, easier and faster data analysis, faster score reporting, and continuous testing, many research questions remain unanswered. For example, how does one improve CAT test security without sacrificing estimation efficiency? How does one detect cheating behavior from an examinee’s response pattern? How does one automatically grade examinees’ performance in a large scale performance based assessment? How does one use test scores to make inferences about examinees’ cognitions? Another big challenge stems from the fact that an unprecedented number of people are taking tests daily, from K-12 educational assessments, college admissions tests, job application and placement tests, professional licensing exams, survey research, psychiatric evaluations, and medical diagnostic tests. As such, the need for new methods is apparent in many aspects of psychometric development. Examples of some new developments are discussed below.

**Large-Scale Automated Test Assembly** Large-scale application of computer-based achievement tests and credentialing exams has generated many challenges to test development. One of these challenges, maintaining content representation in multiple forms, is central to test defensibility and validity. Manually assembling parallel test forms is not only time consuming, but also infeasible when a great number of forms are needed. Utilizing automated test-assembly (ATA) procedures reduces the workload of test developers and ensures the quality of the assembled test forms. ATA methods can be achieved by constrained combinatorial optimization, which involves how to best arrange the controllable elements in large complex systems in order to achieve a specified goal. A typical test-assembly problem can be treated by selecting items so that the assembled test satisfies a certain reliability index (objective function) subject to constraints such as test length and content coverage. Several methods were proposed. According to Wim van der Linden (2005), binary linear programming seems to be a popular method for test assembly due to two reasons: (1) the techniques are well developed within the field of operations research, and (2) some commercial software packages are readily available and user-friendly. Other promising ATA methods include sampling and stratification, weighted deviation, network flow, and optimization methods.

**Automatically Scoring Performance-Based Assessment** A new trend in large-scale assessment is to increase the portion of performance-based tasks in standardized testing. With the rapid development in computer technologies, more and more computer-based tests (CBT) for a variety of innovative constructed-response tasks have become available. Examples of such tasks include writing an essay or diagnosing a computer-simulated patient. However, grading on these complex tasks demands tremendous effort. Due to the subjectivity in human readers’ scoring process, each task requires two or more content experts to review, which is very time consuming and pricey. Moreover, oftentimes there are several thousand or more students taking a given exam. How do we grade such examinations? Can we use automated scoring systems to address the cost issues and make the scoring more consistent? One of the most innovative developments in psychometrics for the last decade is automated scoring of complex tasks.

The Electronic Essay Rater (E-rater) is a technology developed by the Educational Testing Service (ETS) to score essays automatically based on holistic scoring guide criteria (see Burstein et al. 1998). The E-rater is designed to provide a distinct scoring model for each new essay topic. In the first step, a few hundred essays on the same topic were randomly sampled as a “training sample” and then scored by well trained human raters. The human scores are treated as the values of a dependent variable \( Y \). Second, a set of variables are derived statistically from the learning sample, either through Natural Language Processing (NLP) techniques or by simple “counting” procedures. These feature variables, say \( X_1, \ldots, X_n \), are treated as a set of “independent variables” and a linear regression model is established

\[ Y = B_0 + B_1 X_1 + \ldots + B_n X_n + \varepsilon. \]
Third, a stepwise linear regression analysis is performed on the feature variable $X_1, \ldots, X_n$ extracted from the training dataset to identify a subset of features that parsimoniously explains observed variation in the consensus scores. Lastly, the final score prediction for cross-validation sets is performed using these estimated equations. Once the scoring model is established, the scores of the examinees outside the learning sample can be “predicted” by the linear model. Several million essays have been scored by E-rater since it was adopted for scoring the GMAT in 1999, and the technology is being considered for use with the Graduate Record Examination, for graduate school admissions, and the Test of English as a Foreign Language, which assesses the English proficiency of foreign students entering U.S. schools (Mathews 2004).

**Measuring Patient-Reported Outcomes** Conventional clinical measures of disease such as x-rays and lab results do not fully capture information about chronic diseases and how treatments affect patients. In order to get remedial measure, self-completed questionnaires are often administered to patients to assess their subjective experiences such as symptom severity, social well-being, and perceived level of health. Such measurement of patient-reported outcomes (PROs) is important for disease intervention. Many psychometric approaches can be used to meet the needs of clinical researchers across a wide variety of chronic disorders and diseases.

In particular, the CAT technology developed in educational testing can be used innovatively in health-related quality-of-life (HQOL) measures, in which a next item is selected based on the response the patient has given to the previous question. According to Frederic Lord (1971), an examinee is measured most effectively when test items are neither too “difficult” nor too “easy.” Heuristically, if the examinee answers an item correctly, the next item selected should be more difficult; if the answer is incorrect, the next item should be easier. Note that in HQOL applications, the term difficulty is analogous to severity. For example, asking a patient if it is difficult to climb the stairs might measure a lower level of severity than asking if it is difficult to walk 1 mile. Thus, items are tailored to the individual with greater estimation precision and content validity. According to the National Institutes of Health (2003), such a CAT HQOL system would be useful in clinical practice to assess response to interventions and to inform modification of treatment plans.

Psychometric application in HQOL shares many similarities with its use in educational testing, with, for example, reliability and validity being the highest priorities for both. However, different perspectives do exist. For example, the length of the assessment for a particular domain in HQOL is a much greater concern, especially when many domains must be assessed in a population of patients with a chronic disease, because patient burden must be carefully considered. The need for more psychometric research in developing, evaluating, and applying HQOL measures is growing, and undoubtedly, this will advance the field of psychometrics.

**PSYCHONEUROENDOCRINOLOGY**

Psychoneuroendocrinology (PNE) is the study of the dynamic interaction of hormones with the central and peripheral nervous systems, toward the manifestation of behavior, cellular activity, systems-level functionality, and body processes, as well as their clinical applications. PNE is rooted in philosophy and the search for an understanding of the duality or unified nature of the “mind” and “body.” Philosophers wrote copiously about the influence of cognitive and affective processes on physiology, and...
vice versa, and established the intellectual foundation for the development of PNE as a scientific discipline.

Throughout the nineteenth and twentieth centuries, many advances in medicine and science were guided by the pursuit of an understanding of the relationship of the “mind” to the “body.” Many philosophers, physicians, psychologists, and others argued for duality and that the entities were separate and disintegrated. A vocal group of equally qualified and proliferative writers adamantly made a case for integration of the “mind” and “body” and ultimately yielded a coherent and well-articulated philosophy that posited a functional interaction of behavior, the nervous system, and hormones.

PNE evolved from an effort to understand the complex factors that influence human behavior and the development of normality and pathology. This evolution of the development of PNE was not unlike the occurrences that marked the development of many other areas of study (psychoneuroimmunology, psychophysiology, etc.) from a common philosophy of “integration,” resulting in many similarities between disciplines.

Psychoneuroendocrinology can be viewed as extremely similar to psychoneuroimmunology (PNI). Both study the influence of psychological and neurological processes on the manifestation of behavior and disease. However, PNE focuses on endocrine pathways, whereas PNI focuses on immune pathways. Clearly, there is an intimate relationship between hormones and immunity, and it is functionally impossible to discuss the influence of one without discussing the impact on the other. PNE, however, is most often distinguished from other disciplines by a focus on a primary mechanism of action, hormones, on affected cells, tissues, organs, systems, and the body.

Many of the activities of researchers and clinicians from diverse disciplines such as psychiatry, psychology, neurology, endocrinology, molecular and behavioral genetics, and behavioral medicine are often broadly covered under the umbrella of activities that are considered PNE. Topics that are increasingly studied by psychoneuroendocrinologists include but are not limited to glycemic control, chronic pain, infertility and contraception, autoimmunity, Alzheimer’s Disease and other dementias, addiction and compulsive disorders, exercise physiology, cancer, language acquisition and pervasive developmental disorders, marriage and mate selection, reactions to physical and psychological trauma, and racism, inequity, and discrimination.

In 1969 the International Society of Psychoneuroendocrinology was founded in Milan, Italy. Today, this organization represents PNEs across the world and has grown in size and scope. The organization represents the interest of approximately 450 researchers and clinicians toward the goal of promoting, initiating, facilitating, and disseminating into public and clinical forums, basic, clinical, and applied interdisciplinary research in psychoneuroendocrinology.

**PSYCHONEUROIMMUNOLOGY**

Psychoneuroimmunology (PNI) is the study of interactions between the mind, the nervous system, and the immune system. The mind involves thoughts, emotions, and experiences; the nervous system involves the brain, the spinal cord, and nerves; and the immune system involves cells and organs protecting the body from invaders. The mind and the immune system communicate through the peripheral nervous system and through hormones and cytokines, and this communication enables the immune system to be responsive to psychosocial factors and to signal the brain.

The field of PNI is interdisciplinary and has over the years contributed to the contemporary trend toward viewing health and disease as multifactorial. During the 1960s and 1970s, evidence began to accumulate indicating that the immune system could be influenced by psychological phenomena. In 1964 George F. Solomon and Rudolf Moos proposed that the development of rheumatoid arthritis was related to personality factors, advancing the possibility of psychoneuroimmunological phenomena, and Robert Ader and Nicholas Cohen demonstrated in 1975 that conditioning could affect the immune response by pairing taste with an immunosuppressive drug. Today,
there is little doubt that a number of factors—biological, environmental, behavioral, and psychological—can interact to impact the progress and course of many illnesses.

Psychoneuroimmunology research strives to expand the understanding of how psychosocial factors can influence people’s health, either positively or negatively. Research on the influences of psychological factors on the endocrine and immune systems involve examinations of the effects of stressors on these systems, and evidence clearly indicates that psychological and physical stressor exposure can affect the immune system. Stressor exposure also influences the endocrine response, changing levels of hormones such as cortisol. The effects of stressor exposure depend critically on the characteristics of the stressor. Acute stressors that last only minutes can be adaptive as part of a fight or flight response, whereas longer term stressors have less potentially beneficial effects. For example, chronic stressors, such as having a spouse with dementia, have been found to decrease both the cytotoxic and antibody-producing functions of immune cells. Adverse changes in immune functioning have also been associated with divorce, bereavement, unemployment, and other stressful episodes. Research has also demonstrated the importance of healthy social relationships and individual differences that buffer the psychological effects of stress, such as optimism, to better immune function.

Individual differences may not only confer an adaptive impact on the immune system, however. Studies on repression, which is characterized by low self-report of anxiety and avoidance of anxiety-provoking stimuli, but also by high defensiveness, have found associations between repression and poorer cellular immunity. Also, cynical hostility, which reflects suspiciousness, mistrust, and anger, appears to increase the physiological response to stressors involving social interactions and has been associated with increased susceptibility to illness. Clearly, individual differences can impact the immune system in a number of ways.

Studies have shown that stressful experiences can alter elements of the immune response, as well as impact health and disease onset. However, research has not yet convincingly linked these findings together to conclude that alterations in the immune system are in fact the mechanisms through which stressor exposure augments vulnerability to disease.

**PSYCHOPATHOLOGY**

*Psychopathology*, also referred to as mental disorder, is considered present when a behavior pattern or emotional state causes an individual clinically significant distress, dysfunction, or impairment in social, occupational, or other important areas of functioning or is widely deviant from social or cultural norms. This conceptual definition is somewhat subjective and might be difficult to apply in specific cases, in part because behavior patterns found to be acceptable according to the norms of one group or culture might be seen as abnormal or deviant in another. For example, self-mutilation is seen as an expression of piety in some cultures and as a sign of pathology in others.

An alternative means of defining psychopathology is to follow a more objective guide to psychiatric diagnosis in which specific symptom criteria are assessed for a standard set of mental disorders. Two related diagnostic protocols contain these specific criteria: *The Diagnostic and Statistical Manual of Mental Disorders* (DSM, American Psychiatric Association), and *International Classification of Diseases* (ICD, World Health Organization). Table 1 displays DSM criteria for the diagnosis of schizophrenia.

CATEGORIES OF MENTAL DISORDER

There are several broad categories of mental disorder representing differences in severity or degree of maladaptive-ness. Psychotic disorders are among the most severe in that such patients are said to be out of touch with reality. For example, people suffering from schizophrenia often experience hallucinations, aberrant perceptions, such as hearing voices that others do not hear or seeing things others do not see while believing them to be actually occurring. They might also experience delusions, false beliefs, such as that they are being pursued by aliens because they hold some secret of the universe. Another defining characteristic of schizophrenia is the presence of thought disorder, in which patients are unable to maintain a coherent train of thought as their minds jump from topic to topic without apparent awareness that they are doing so.

Bipolar disorder (formerly known as manic depres-sion) involves alternating episodes of mania in which patients are hyperactive, feel elated, and need little sleep. They might also experience delusions consistent with their mood, such as believing that they are invincible, brilliant, or have a theory that will save the world. Ultimately, they lapse into severe depression and may be unable to function at all while experiencing delusional beliefs, such as that they are dead or that their bodies are hollow.

Neurotic disorders are of a lesser degree of severity than the psychotic disorders yet cause significant distress and dysfunction to millions of people. Among the most prevalent of these are the anxiety disorders, which include the phobias, panic disorder, obsessive-compulsive disorder, and post-traumatic stress disorder. Mood disorders, such as major depression, are also quite common and can be episodic or continuous if not treated.

Organic mental disorders occur as a result of brain injury or disease, including dementia due to Alzheimer’s disease, head injury, Parkinson’s disease, or ingestion of toxic substances such as alcohol or inhalants. The primary areas of dysfunction in organic mental disorders include impaired abstract reasoning, lack of judgment, and impulsivity. In dementia in particular, memory deficit for new material is pronounced, and in more advanced stages entails loss of recall of previously familiar information, including recognition of family members and friends. Organic mental disorders can also involve delusions and depressive symptoms.

One in four American adults age eighteen and older has a DSM-diagnosable mental disorder within any given year. However, only one in seventeen (6 percent), suffers from serious mental disorder, such as schizophrenia or bipolar disorder. Table 2 displays prevalence figures for several of the more common mental disorders in the adult U.S. population. Approximately 20 percent of children are also estimated to have a diagnosable mental disorder, but less than 9 percent are considered serious. These prevalence figures are only general averages that vary by gender, by culture and ethnicity, and from rural to urban areas. Some mental disorders found only in certain cultures are said to be culture bound, such as “running amok” in Malaysia.

THE ROLE OF GENES

Family and twin research demonstrates that there are genetic components that predispose some people to mental disorders. The closer one’s relationship to a family member with schizophrenia, for example, the more likely that person will develop the disorder. Children born of two schizophrenic parents have a 46 percent chance of developing schizophrenia at some time in their lives. Similarly, if one member of an identical twin pair becomes schizophrenic, in 48 percent of cases the co-twin will also become schizophrenic. The fact that all such identical co-twins do not become schizophrenic indicates that more than genetics is involved in developing the illness. Various environmental factors hypothesized to be involved along with the genetic predisposition in determining who becomes mentally disordered include family and life stresses, early traumatic events, and maternal illnesses at critical periods during gestation. Some anxiety, depression, and substance abuse disorders also have genetic liabilities, although the genetic contributions in most cases are not as strong as for schizophrenia and bipolar.

ASSESSING MENTAL DISORDERS

Psychological assessment is the process of examining a patient to understand the range of possible problems or symptoms that can then lead to a diagnosis and treatment plan. One common assessment process is administration of a mental status examination, which is a semi-structured sur-

CONSEQUENCES OF MENTAL DISORDERS

The consequences of being mentally ill are great both for the individual and for society. For the individual, there is a strong social stigma attached to mental illness that may manifest itself in many ways, such as employment discrimination, which is greater for the mentally disabled than for the physically disabled. Fully half of employers are reluctant to hire someone with a psychiatric history or someone currently taking medication for depression.

The economic consequences for society are great as well. The World Health Organization estimates that mental illness accounts for 15 percent of the burden of disease (years lost as a result of premature death and disability) in developed countries—more than the burden caused by all types of cancers. For women, depression causes more disease burden than any other illness. In fact major depression is the leading cause of disability worldwide among individuals five years of age and older.

TREATMENTS

Numerous treatments for mental disorders have emerged, varying according to the state of medical science at any given time. When mental disorder was thought to be caused by malevolent spirits infesting the brain, treatment consisted of chipping holes in the skull (trephining) to let the evil spirits out. When overcharged blood vessels were thought to be the cause, bloodletting was prescribed to reduce pressure on the brain and to bring patients back to their senses. Although these forms of treatment are no longer used in European and North American medicine, the focus remains on the brain. Brain processes are targeted to be changed through social, psychological, or biochemical means; the bloodstream transports chemicals to the neuroreceptors in the brain to effect therapeutic emotional, behavioral, and cognitive changes.

In the late nineteenth century Sigmund Freud pioneered the use of psychological processes to effect change in mental and emotional states. His original procedures have become the subject of much debate in the fields of psychology and psychiatry, but research demonstrates that other psychological treatment procedures are quite effective in treating a number of highly prevalent mental disorders. One group of treatments, referred to as cognitive behavioral therapy, focuses on assisting patients to systematically alter their thinking processes and their behaviors in ways that effect changes in the emotions and behaviors that led to and perpetuate their dysfunction. These procedures have been particularly successful in treating anxiety disorders and depression and are as effective as medications for treating these conditions.

Psychotropic drugs are perhaps the most widely used treatments for mental disorders in the early twenty-first century. Antianxiety medications, such as the benzodiazepines (e.g., Xanax, Valium, Atavan), effectively reduce felt anxiety but have a drawback in that they are potentially addictive. These antianxiety drugs work with the GABA system of neurotransmitters, which work to inhibit nerve transmission in areas of the brain that relate to anxiety.

A widely used class of antidepressants, some of which also have antianxiety properties, are the selective serotonin reuptake inhibitors (e.g., Prozac, Zoloft, Paxil). These drugs increase the availability of the neurotransmitter serotonin in the brain and relieve depression and some anxiety.

Psychotic conditions, such as schizophrenia, are treated with several types of antipsychotic drugs (e.g., Thorazine, Haldol, Clozaril, Risperidol). These medications tend to block the neurotransmitter dopamine, which is thought to underlie schizophrenia symptoms and
related psychotic states. Bipolar disorder, mania, is now treated with drugs, such as Geodon and Seroquel, that tend to reduce the hyperactive manic state and associated psychotic delusions. Although they are largely successful in reducing psychotic symptoms, prolonged use of these drugs can lead to severe movement disorders, such as Parkinsonism and tardive dyskinesia.

*Psychosurgery*, brain surgery to affect changes in mental or emotional states, was widely used until the advent of antipsychotic drugs in the mid-twentieth century. Since then it has been used rarely, only in cases unresponsive to standard therapies. *Electroconvulsive therapy* continues to be used in severe cases of depression, in which patients are unresponsive to psychotherapy or antidepressant medications. *Transcranial magnetic stimulation* is a promising new experimental procedure for treating severe depression and involves applying powerful electromagnets directly to the skull.

**PSYCHOSOMATICS**

The term *psychosomatic* relates primarily to a physical concern, symptom, or illness of the body originating from emotional and thinking processes. The *psychosomatic* is born from an appreciation that the mind influences the body and the body influences the mind, and that pathology is the multifactoral product of biological, psychological, and social processes.

Historically, *psychosomatic* referred to the adverse impact that psychic and hysterical struggles exerted onto physical functioning and illness. Many illnesses (asthma, tuberculosis, allergies, chronic headaches, epilepsy, fibromyalgia, hypertension, interstitial cystitis, irritable bowel syndrome, etc.) were initially, in a pejorative manner, consistent with the zeitgeist of the times, conceptualized and evaluated as being hysterical reactions to psychic disturbances. In this mostly psychodynamic context promoted by Josef Breuer (1842–1925), Sigmund Freud (1856–1939), and other theorists, the term *psychosomatic illness* was used to describe physical symptoms and diseases whose primary etiologies were emotional and mental processes.

More recently, a psychosomatic illness is conceptualized as one whose etiology cannot be described by physical or organic causes or whose etiology is idiopathic. In cases of unknown or ambiguous onset, anger, hostility, repressed sexual tension, and guilt are often ascribed as etiological precipitants of disease. In other cases, even when significant biological factors clearly influence the onset and course of illness but psychic disturbance is saliently present (depression, anxiety, hostility, etc.), the term *psychosomatic* is also used to reference the interaction of psychiatric and biological processes on symptom and disease manifestation.

Consequently, psychosomatic illnesses refer to symptoms or diseases that have psychic onset or psychic influences on the course, duration, or resolution of symptoms. Notably, psychosomatic illnesses have real symptoms and are diseases with real physical manifestations. This distinction is important in comparison to disorders where motivational and conscious factors characteristic of the patient influence the reporting of feigned diseases. For example, as a psychosomatic manifestation, the gastrointestinal symptoms associated with irritable bowel syndrome (diarrhea, constipation, or abdominal pain and cramping) may increase during periods of prolonged or intense emotional stress. Similarly, the magnitude of an asthmatic onset may be reduced with relaxation, focused deep breathing, or other behavioral techniques that alter physiology.

As in the previous example, psychosomatic illnesses have brought about a focus on interventions that exploit the known relationship between the mind and body. The study of such interventions is known as *psychosomatic
Psychosomatics, Social

Psychosomatic medicine, and the journal that is most aligned with this pursuit is *Psychosomatic Medicine*, the official journal of the American Psychosomatic Society. In its basic conceptualization, psychosomatic medicine is the science of treating the mind and body toward the reduction of morbidity and mortality.

The methodology of inquiry, as well as the topics explored by clinicians and researchers who practice and study psychosomatic medicine, have evolved over many years. Most often, the scientific inquiry and reviewers’ and editors’ choices for published articles have been reflective of scientific and societal priorities at the time.

One of the best discussions of this evolution in methodologies and priorities for clinicians and researchers appears in a review article in *Psychosomatic Medicine* of papers published in the journal on the topic of pain from 1940 to the end of the 1990s (Keefe et al. 2002). The authors found that in the 1940s “case studies” were one of the major methodologies published on the topic. However, by the 1950s the number of such publications had decreased by more than 50 percent, and by the 1970s case studies were rarely published in the journal. In contrast, the number of published studies exploring the role of personality traits and individual differences on pain was relatively small in the 1940s, but it had increased more than 400 percent by the end of the 1990s.

More reflective of deeply rooted societal beliefs about race and ethnicity, there were no studies published on the impact of race, ethnicity, and culture on pain in the 1940s, 1950s, or 1960s in *Psychosomatic Medicine*. Two such studies appeared in the journal in the 1970s, and only one was published in the 1980s. Only four articles were published on racial and ethnic influences on pain in the 1990s, for a total of seven across sixty years. This lack of published studies is interpreted as demonstrative of the infancy of general interest, knowledge, and understanding of racial and ethnic influences on medical outcomes in society, medicine, and psychosomatic medicine.

Issues of gender differences in psychosomatic illnesses have a much more robust and long history within psychosomatic medicine. The first studies of gender on the prevalence and experiences of pain appeared in *Psychosomatic Medicine* in the 1950s. There was a steady number of publications on this topic throughout the 1950s, 1960s, and 1970s, with a rise in the 1980s and a fourfold increase in the 1990s. A similar pattern in the number of published articles after 1980 can be seen for pain induction studies and pain treatment studies.

The current state of psychosomatic medicine seems embedded in the historical roots of the discipline and is focused on such issues as coping and the impact of psychological constructs like depression and anxiety on biological, neuroendocrine, and other symptom and disease-related outcomes. Although the horizon is bright with an increased number of studies that focus on individual differences and the impact of demographic factors like race, ethnicity, age, and geographic region on disease-related outcomes, there is still much work to be done.

As evidence of a new global environment and a terrorism-conscious world, experts in psychosomatic medicine are increasingly involved in the development of health policies and are advocates for the collaboration between medical practitioners and public health officials toward more effective responses to international and local threats. Many government officials have begun to recognize the unique skill sets that experts in the field possess and are utilizing these skills to more effectively implement public health policy. The use of advanced statistical methodologies by researchers in psychosomatic medicine allows for the development of more ecologically valid predictive models of human health and behavior. Journals such as *Psychosomatic Medicine* and *Psychosomatics* highlight the zeitgeist of the discipline and provide a forum for scientific communication among researchers.

**PSYCHOSOMATICS, SOCIAL**

Social psychosomatics attempts to explain how social psychological processes—thoughts, feelings, and emotions—influence bodily changes. More generally, the field of social psychosomatics seeks to explore the links between social processes and physical illness. This field of study is principally concerned with the influence of emotional...
stimuli on physiologic changes. This relationship is bidirectional, with emotions influencing biological changes and physical health influencing emotion. Indeed, numerous studies have shown that overall health is the best predictor of happiness in adults.

Interest in the relationship between emotions and bodily processes extends as far back as Socrates and Hippocrates, who believed that emotion was a critical influence on health and disease. Modern day social psychosomatics is an interdisciplinary field that combines research from the fields of psychology, sociology, anthropology, medicine, and many others. The “fight or flight” response is well known throughout both the social and medical fields. Like other animals, our bodies release adrenaline in preparation to either face or flee from an environmental stressor. While this was at one point evolutionarily adaptive, and remains so in situations requiring split-second decisions, long-term activation of this stress response may have detrimental health consequences.

PSYCHONEUROIMMUNOLOGY

One particular branch of social psychosomatics that has been particularly influential in recent years is psychoneuroimmunology. This term describes the influence of psychological processes on immune system functioning. In particular this field of study examines the influence of stress on the susceptibility to infectious disease processes, such as the common cold. According to a 1991 study by Sheldon Cohen, David A. J. Tyrrell, and Andrew P. Smith, one illustration of this approach is known as a “viral challenge.” In such a study participants are quarantined in a laboratory setting for a particular period of time. During this time participants undergo medical exams, complete questionnaires assessing their physical and mental health as well as health behaviors, and respond to psychosocial measures that describe various aspects of their personality and the amount of stress they are currently experiencing. Following this initial assessment, participants are given nasal drops containing a strain of a virus or a placebo. For the next few days, participants undergo daily examinations to assess for the presence of viral symptoms and the number of tissues used are counted and weighed. The “viral challenge” technique allows the impact of stress on susceptibility to the common cold to be analyzed, while controlling for exposure to the illness. The paradigm also enables the study of other factors thought to influence susceptibility to illness, including personality variables.

Another means of exploring the influence of stress on health is to examine viruses that are usually held latent by active immune systems, but that may return when the person is exposed to high levels of stress, such as a major life event. One virus that illustrates this scenario is the herpes virus, thought to be responsible for diseases such as cold sores, genital lesions, and mononucleosis. While the virus is typically suppressed by a strong immune system, it will flare, and studies have supported the idea that there is a relationship between negative emotional states, such as stress, and flare-ups.

HOW PERSONALITY MAY AFFECT HEALTH

Another indication of the impact of mind states on the body are diseases that seem to be strongly connected to certain personality types. For example, people who display high levels of aggression, hostility, or anger seem to be more likely to develop cardiovascular problems, while those people who are shy or socially isolated seem to be more likely to develop immune and metabolic illnesses.

While most research has focused on the negative repercussions certain emotions or life events may have on physical health, other research has focused on positive emotions that can foster health and well-being. Indeed studies have shown that factors such as high self-esteem, a strong sense of self-efficacy, and resilience predict positive changes in mental and physical health. Other positive factors that have been studied are hope, optimism, social support, and positive interpersonal relationships. Indeed studies have shown that these positive qualities can hasten recovery from serious injury or illness, while people who do not have these qualities are at greater risk for developing illnesses such as heart disease and cancer. A 2006 review by Sheldon Cohen and Sarah D. Pressman demonstrated an ongoing association between positive affect and lower rates of morbidity, illness, pain, and increased longevity, while John C. Barefoot and colleagues in their 2005 study found that people with heart disease who had larger and more diverse social networks had better outcomes.

In summary the field of social psychosomatics explores the connection between social processes and physical health, seeking to discover both the consequences and benefits of the link between our social world and our physical beings, as well as examining potential factors that may reduce or exacerbate the link.

**PSYCHOTHERAPY**

Psychotherapy is the treatment of mental illness, emotional difficulties, or behavioral problems through usually non-invasive psychological means. It is based on the premise that human psychological suffering can be alleviated by speaking and listening. At its core, psychotherapy involves the interpersonal interaction between a trained professional and a suffering individual. Collectively, the varied forms of psychotherapy are often referred to as “talking therapies.” The specific techniques used in any psychotherapy depend largely on the theoretical orientation of the psychotherapist. Most approaches to psychotherapy can be traced in origin to one of the following schools: psychoanalytic, behavioral, cognitive, or humanistic. In practice, however, much of what is called psychotherapy today involves an evolving, fluid, and personalized use of techniques that depend on the specific problem, the professional’s training, and the sufferer’s needs. The goals of all types of psychotherapy typically involve the reduction of symptoms (e.g., depression, anxiety), altering maladaptive patterns of living (e.g., alcohol abuse, compulsive gambling), and/or improvement in specific areas of life functioning (e.g., increased capacity for work, creativity, or relationships).

The advent of modern psychotherapy can arguably be attributed to the work of Franz Anton Mesmer (1734–1815). Though few, if any, of his ideas would be recognized today as sound practice, his work marked an important shift from religious theories and explanations of healing (i.e., exorcisms) to theories based on scientific understandings of the time. The trance-like state Mesmer induced in individuals (still known colloquially today as being “mesmerized”) was the precursor to hypnosis, a practice that French neurologist Jean-Martin Charcot (1825–1893) began using more specifically to treat patients with psychological difficulties. As a student of Charcot’s, Sigmund Freud (1856–1939) first began using hypnosis to treat patients before he abandoned it for what would later become his revolutionary method of psychoanalysis. Decades of theoretical evolution of psychoanalytic theory has spawned a vast array of psychotherapies.

Though a contemporary of Freud’s, Ivan Pavlov’s (1849–1936) work represents a different yet important developmental line in the understanding of human behavior and learning. Known for his work studying the reflexive behavior of dogs, Pavlov discovered how certain behavioral responses could be experimentally brought about, or “conditioned,” by pairing specific stimuli with other naturally occurring behaviors. This principle was used by American psychologists John B. Watson (1878–1958) and B. F. Skinner (1904–1990) in the clinical application of behaviorism, behavior therapy, and then to cognitive and cognitive-behavioral therapy. Historically, behavioral and cognitive psychotherapies have been viewed as an important counterargument to the earliest psychoanalytic ideas and techniques. In fact, the trailblazers of the behavior and cognitive psychotherapy movement, Albert Ellis (b. 1913) and Aaron Beck (b. 1921), both had early psychoanalytic training and interests.

**PSYCHOANALYSIS**

Developed by Sigmund Freud, psychoanalysis is often recognized as the first modern form of psychotherapy. It is based on the assumption that psychological symptoms are caused by unconscious conflict often rooted in one’s early childhood experience. The aim of psychoanalysis is to bring unconscious conflicts into conscious awareness through the processes of introspection, insight, and interpretation. In a collaborative effort, the patient and therapist examine and try to resolve these conflicts, freeing the patient to live a more adaptive, healthy, and fulfilling life.

Freud discovered that examining the unconscious required some special tools. Foremost of these was the process of “free association,” the uncensored report of all thoughts and fantasies, regardless of content. What seemed potentially irrelevant, tangential, or embarrassing to the patient was seen by Freud to have disguised connections and meanings that once understood would help reveal unconscious conflicts and reduce suffering. To pro-
mote free association, an analytic couch was often used, with the analyst sitting behind the couch and listening to the patient. Freud also viewed dreams as disguised and symbolic representations of unconscious conflicts, which could be useful in the psychoanalytic process. The interpretation of these conflicts brought about change, according to Freud.

As Freud's understanding of psychoanalytic theory evolved he began incorporating such ideas as transference, resistance, and defensive mechanisms into his theory of cure. The practice of psychoanalysis continues to evolve today in ways that maintain, reject, and expand some of Freud's original principles. Although traditional psychoanalysis (usually four to five appointments per week for several years) is not as popular as it was in the first half of the twentieth century, at the beginning of the twenty-first century it remains a sought-after treatment modality for some people. A more popular variant of psychoanalysis is face-to-face psychoanalytic psychotherapy, which uses many of the same principles as psychoanalysis but is less frequent (usually one to two appointments per week). In the psychoanalytic community, psychoanalysis is viewed as the treatment of choice for a wide range of psychological difficulties, including depression, anxiety, and personality disorders. Though the cost and length of treatment has been criticized as being prohibitive for many individuals, proponents of psychoanalysis and psychoanalytic psychotherapy argue that benefits are more comprehensive and longer lasting than other forms of treatment.

BEHAVIORAL THERAPY

Behavior therapy emphasizes the scientific understanding of observable behaviors, rejecting the importance of self-awareness, insight, and the unconscious as valued in psychoanalytic techniques. The goal of most forms of behavior therapy is to increase desired behaviors and decrease undesired ones. It is a collective group of therapeutic techniques based on systematically researched theories of learning and behavior. For example, Pavlov's discovery of "classical conditioning," or Pavlovian conditioning, led to an increased understanding of how certain behaviors could be learned. In his experiments with dogs, Pavlov found that the repeated pairing of a bell immediately preceding the presentation of meat powder would eventually "condition" the dogs to salivate when the bell was later presented alone (without the meat powder). John B. Watson's (1878–1958) famous "Little Albert" experiment demonstrated how fear of a non fear-inducing white rat could be conditioned in a toddler boy by the repeated pairing of a loud noise with a the presentation of the rat. While the increase of salivation in dogs or the induction of fear in infants are hardly desired outcomes of modern psychotherapeutic techniques, these principles of classical conditioning have had a far reaching influence on subsequent developments of different forms of behavior therapy.

"Systematic desensitization," for example, is a behavioral therapy technique that uses principles of classical conditioning to help gradually alleviate specific phobias (e.g., fear of flying) or reduce the symptoms of certain anxiety disorders. "Flooding" (also called exposure therapy) is another form of behavior therapy used to help reduce anxiety by exposing an individual to a feared stimulus until the anxiety is extinguished. Though not commonly used in modern day, "aversion therapy" is a controversial behavior therapy technique that pairs unwanted behaviors with unpleasant results in order to reduce the behavior (e.g., pairing alcoholic beverages with a chemical substance that causes nausea). Other behavioral approaches involve principles of "operant conditioning" that Skinner was most noted for. Operant conditioning relies heavily on ideas of reinforcement and punishment in the service of increasing desired behaviors and decreasing unwanted behaviors.

Behavior psychotherapies tend to be directive, specific, and symptom focused. They are most popularly associated with the treatment of specific phobias, various anxiety disorders, or maladaptive behaviors (e.g., addictions, pedophilia). While research suggests that these techniques can be highly effective, especially in the short term, there is some debate as to how lasting the effects can be. A criticism of a strict behavioral approach to treatment is that it does not address underlying causes of the behaviors. The principles of behaviorism and behavioral psychotherapy are often used most successfully in conjunction with other theoretical approaches.

COGNITIVE THERAPY

Since the 1960s cognitive psychotherapy has been the predominant force in the treatment of many psychological difficulties. The basic assumption of all forms of cognitive therapy is that thinking impacts feeling. For example, cognitive therapists posit that an individual may be feeling depressed because of certain thoughts the person has (e.g., "I am not good enough"). In contrast to behaviorism's focus on observable behaviors, the aim of cognitive therapy is to address, challenge, and alter maladaptive thoughts and cognitions. This can be done in many ways.

Developed by Ellis, Rational Emotive Therapy, also known as Rational Emotive Behavior Therapy, is a confrontational form of cognitive therapy that involves active and direct confrontation of an individual's irrational beliefs. This type of intervention was intended by Ellis to be somewhat jarring to patients so as to highlight how individuals' thoughts and beliefs were irrational appraisals of events that led to self-imposed suffering (e.g., depres-
sion, anxiety). As such, alleviation of symptoms came about by attacking these irrational thoughts directly.

Beck is known for developing a less confrontational, gentler approach to cognitive psychotherapy. Beck’s work, and many approaches that follow, focuses on correcting errors of reasoning called “cognitive distortions.” These distortions are said to create and maintain negative feelings such as anxiety or depression. For example, a young man engages in the cognitive distortion of catastrophizing (e.g., assuming the worst case scenario) when he believes that his public speaking will provoke unbearable anxiety and illicit embarrassing ridicule. In reality, however, the experience may just be uncomfortable. A cognitive therapist would address with this young man the distortions of his thinking. Other cognitive distortions include “overgeneralization,” “all-or-nothing thinking,” and “jumping to conclusions.” All of these distortions are automatic in nature and the process of cognitive psychotherapy works to reprogram these thoughts into more adaptive ones. Technically, cognitive psychotherapy tends to be directive with an emphasis on self-monitoring, problem solving skills, behavioral experiments, and improved decision making. Many cognitive therapists utilize homework assignments to encourage patients to continue monitoring their thoughts and feelings when outside the consulting room.

The term cognitive-behavioral psychotherapy is often used to describe the natural and practical mix of many of the cognitive and behavioral techniques described. In general, cognitive and cognitive-behavioral therapy utilize a much more structured and guided approach. It has proven to be a highly effective, efficient, and often time-limited treatment of many psychological disorders. Its structure also lends itself well to empirical investigation. Cognitive and cognitive-behavioral psychotherapy is the predominant form of psychotherapy being practiced in the United States today.

**HUMANISTIC THERAPY**

Having its roots in existential philosophy, humanistic psychotherapy is based on the ideas and practice of Abraham Maslow (1908–1970) and Carl Rogers (1902–1987). Often referred to as a “third force” of modern psychology and psychotherapeutic technique, humanistic psychotherapy represents an alternative to the larger psychoanalytic and cognitive-behavioral approaches. Both Maslow and Rogers focused on the ideas of psychological growth and deemphasized the notion of mental illness. Developed in the 1960s, humanistic psychotherapy posits that humans have an innate desire to maximizing personal growth and fulfillment, a goal termed by humanistic thinkers as “self-actualization.” The blocking of self-actualization is viewed by humanistic therapists as the source of psychological suffering.

Perhaps more than any other clinician, Rogers’s person-centered therapy illuminated the more universally practical components of psychotherapy, regardless of orientation. His focus on a genuine, empathic, and honest relationship between therapist and sufferer has been viewed as instrumental across many therapeutic disciplines. Humanistic psychotherapy tends to be non-directive. The humanistic psychotherapist focuses on the patient’s current feelings and experiences. The goal of Rogers’s type of psychotherapy is to listen in an empathic way that allows the patient to feel heard and understood. It was this understanding, Rogers believed, that helped patients navigate personal roadblocks and live more fulfilled and meaningful lives. Other important variants of humanistic psychotherapy were practiced by Rollo May (1909–1994), Victor Frankl (1905–1997) and James Bugental (b. 1915).

**OTHER PSYCHOTHERAPIES**

The various practices described share in common the most traditionally recognized form of psychotherapy: one trained professional listening and speaking with a suffering individual. There are, however, other forms of psychotherapy that deserve mention. As early as the 1940s, psychotherapy in a group setting was an accepted form of treatment.

The unique benefits of the interpersonal experience coupled with the increased patient-to-therapist ratio maintains group psychotherapy as a popular alternative to individual psychotherapy. Support groups led by lay persons or fellow sufferers, such as Alcoholics Anonymous, remain a popular treatment choice for individuals. Specific psychotherapies have been designed to work with families, couples, or even in industrial settings. Play therapy is often a method used by practitioners working with children. There are also different forms of psychotherapy that involve the use of music or art. The variety of problems, populations, theoretical orientations, and modalities, coupled with each psychotherapist’s individual style, makes the number of different types of psychotherapy virtually endless.

**BIOLOGICAL CONSIDERATIONS AND RESEARCH**

The biological treatment of psychological distress has become inextricably linked to current ideas about psychotherapy. The 1950s marked an explosion of scientific research that led to new understandings about the connection between brain chemistry and psychological disorders. Most notably, the advent of psychotropic medication demonstrated that medicines could influence individuals’ thinking, feelings, and behaviors in ways that brought...
about relief of symptoms. This development has drastically changed the way people suffering from mental health issues receive treatment. Though it has not supplanted psychotherapy as a treatment modality, psychopharmacology has proven to be an important aspect of treating many disorders. Findings suggest that for most mental health issues, a combination of psychotherapy and medication is often more effective than either alone or none at all.

Critics of the biological approach often state that medication alone treats only symptoms and does not address underlying, more psychological causes, often leaving individuals dependent on medications to maintain a sense of mental health. The effectiveness and efficiency of symptom relief that some medication has demonstrated, however, solidifies the medical treatment of mental illness as an important modality that is here to stay. That said, new developments in neuroscience, brain imaging, and research techniques are beginning to demonstrate how psychotherapy alone can alter brain chemistry. This nascent line of research has begun focusing the historically fuzzy distinction between mind and body that has puzzled philosophers and scientists for thousands of years.

Psychiatry itself is a biologically oriented field. As compared to other mental health fields such as clinical psychology, counseling psychology, and social work, modern psychiatric training involves relatively little instruction or experience in the practice of psychotherapy. This has not always been the case. At the height of its popularity in the United States, psychoanalysis was practiced almost exclusively by psychiatrists. It was only in the late 1980s that psychologists, social workers, and counselors were first accepted into American psychoanalytic training institutes. Although some psychiatrists practice various types of psychotherapy as part of their profession, most do not and the balance of psychotherapy practice has shifted to non-medically trained professionals. As a medical profession with prescription privileges, however, psychiatrists are the most knowledgeable and well-trained in the area of psychotropic medication and the biological treatment of mental illness.

In the study of mental health treatment there is a growing call for the introduction and dissemination of psychotherapy approaches to be scientifically sound and have evidence-based proof of effectiveness. This comes from a social value of consumer protection as well as the financial pressures inherent in increasing health care costs. The structured nature of cognitive and behavioral psychotherapy techniques have made these forms of treatment better suited to traditional experimental designs and standardization, whereas the less structured and more individualized psychoanalytic and humanistic treatments present more complicated research challenges. This makes comparing the effectiveness of one type of therapy versus another understandably problematic. What constitutes proof is also a matter of debate among researchers, practitioners, and patients alike. While the scientific study of psychotherapy process and outcome likely will continue to illuminate and inform the public about treatment options, it is important to always consider the limitations of such research.

Debates between theoretical camps of psychotherapy have had a history of contention, each, at times, extolling the virtues of their own techniques and criticizing the deficits of the others. This debate has also been informative, propelling the understanding of what helps troubled people feel better. In some ways the debate is like the fable of the six blind men asked to describe an elephant to one another. Having only the sense of touch, one man described the smooth coolness of the ivory tusk, another the furrowed curve of the trunk; a third the wispy tuft of the tail, and so on. Each man could hardly believe that he was describing the same thing as the other.

PSYCHOTROPIC DRUGS

Psychoactive drugs are substances prescribed to affect one's behavior, emotions, or cognition. They can be categorized into the following drug classes: antipsychotics, antidepressants, anxiolytics, mood stabilizers, and stimulants. Psychotropic drugs are routinely used to treat various mental disorders, and their efficacy is determined by how well the drug decreases the presenting symptoms of a disorder, as well as the presence or absence of side effects.

PSYCHOTROPIC DRUG CLASSES

Antipsychotics are prescribed primarily to manage the symptoms associated with schizophrenia, autism, and other developmental disabilities. On occasion, they are used in combination with other drugs to treat depression and bipolar disorder. There are two classes of antipsychotic drugs: typical and atypical. The difference between these two groups lies in their mechanism of action. Typical antipsychotics are highly selective for dopamine receptors, specifically D2 receptors. Unfortunately, because of this selectivity, movement disorders (e.g., tardive dyskinesia) are a side effect of the typical antipsychotics. Given this undesirable side effect, atypical antipsychotics were developed. They differ from the typical antipsychotics in that they have a lower affinity for D2 receptors, and affect other neurotransmitter systems such as serotonin. Atypical antipsychotics have significantly fewer motor side effects; however, weight gain is an issue.

Antidepressants are used in the treatment of depression, post-traumatic stress disorder, anxiety, and obsessive compulsive disorder. There are three major classes of antidepressants prescribed: monoamine oxidase inhibitors (MAOIs), tricyclic antidepressants (TCAs), and selective serotonin reuptake inhibitors (SSRIs). The best known of these is the SSRI. SSRIs exert their effect by blocking the reuptake of serotonin from the synapse into the presynaptic neuron, thus increasing its availability postsynaptically. Physiological side effects associated with SSRIs are usually minimal and transient, with the exception of sexual dysfunction. Increases in suicide ideation in adolescents treated with SSRIs have been reported, and thus SSRIs are not generally recommended for use with this population. Despite their popularity, SSRIs have not been found to be any more effective at treating depression than any other antidepressant.

Anxiolytics are prescribed to treat anxiety and sleep disorders. There are two classes of anxiolytics, benzodiazepines and non-benzodiazepines. Benzodiazepines exert their effects by increasing the efficiency of gamma-aminobutyric acid (GABA), an inhibiting neurotransmitter. These drugs are fast-acting, and side effects include the potential for physiological addiction. Non-benzodiazepines include buspirone, which exerts its effect via activity at serotonin receptors. The potential for abuse with non-benzodiazepines is less than with benzodiazepines, but they also appear to be less effective at treating anxiety disorders than benzodiazepines.

Although lithium is the only drug used specifically for the treatment of bipolar disorder, anticonvulsants such as lamotrigine also have been demonstrated to have mood-stabilizing properties. At the present time, the neuropharmacology of these drugs in the treatment of mood disorders is not understood, and both lithium and certain anticonvulsants require routine blood monitoring to guard against toxicity.

Finally, stimulants are prescribed to treat attention disorders such as attention deficit/hyperactivity disorder (ADHD). These drugs operate by increasing the availability of dopamine, epinephrine, norepinephrine, and/or serotonin. Side effects associated with stimulants are decreased appetite and difficulty sleeping.

EIFICACIOUS USE OF PSYCHOTROPIC DRUGS

Prior to the advent of psychotropic drugs in the late 1940s, treatment of psychiatric disorders included admittance to asylums, physical restraints, and psychoanalysis. Consistent and effective results of treatment were often elusive. Advances in technology and the convergence between the fields of psychiatry, neurology, genetics, and neuroscience have made it possible to evaluate the therapeutic effects of psychotropic drug use, and to make predictions about who will respond well to their use. The application of neuroimaging techniques such as functional magnetic resonance imaging (fMRI) to drug evaluation allows assessment of changes in cerebral blood flow, volume, and oxygenation as a function of psychotropic drug use that may provide an indication of the efficaciousness of psychotropic treatment in disorders such as schizophrenia and depression (Tracey and Wise 2001).

Psychopharmacogenomics is another approach that attempts to predict efficacious drug treatment (Malhotra, Murphy and Kennedy 2004). The goal is to identify polymorphisms or mutations of genes involved in receptor function, pharmacokinetics, and pharmacodynamics, to determine who is at an increased risk for experiencing side effects of psychotropic drugs. With each of these technological advances, the aim is to improve prescribing practices and provide individualized, effective treatment while ensuring quality of life.

PUBLIC ADMINISTRATION

Public administration is a practice of government, an academic study, and a political reform movement. While public policy is the study of the process of making laws and government programs, public administration implements these policies and studies and seeks to improve this implementation.

The administration of King Frederick William I of Prussia (1688–1740) in the eighteenth century and an 1887 journal article by political scientist and future U.S. president Woodrow Wilson (1887) emphasized the need to create and use a nonpolitical, career civil service in order to implement policies more honestly and efficiently. With the rapid increase in industrialization and urbanization in the United States during the late nineteenth and early twentieth centuries, public administration developed further as an academic study at major universities and as a political reform movement within federal, state, and local governments. In particular, the public administration movement wanted to transform most entry-level government jobs from politically appointed positions to merit-based civil service positions determined by standardized tests and protected from improper political influence. The Pendleton Act of 1883 began merit-based testing and hiring for federal jobs, and state and local governments gradually adopted similar reforms.

During the twentieth century, public administration also wanted to apply the methods, organizations, and values of business administration to government. In particular, people who wanted to “run government like a business” wanted public administration, especially in local government, to be as cost efficient, productive, and professional as corporations in managing personnel, providing goods and services, and spending funds. This perspective and objective are especially evident in the city manager form of government. This is a type of government in which a city or town council hires a city manager to exercise the administrative, personnel, and budgetary powers typically exercised by elected mayors in other forms of local government. The Budget and Accounting Act of 1921, the recommendations of the Brownlow and Hoover commissions, and the Civil Service Reform Act of 1978 reflected similar business-like practices and values in personnel and budgetary management as they applied to the federal government. According to the book *Democracy and the Public Service* by Frederick C. Mosher (1968), the Brownlow commission of 1937, chaired by political scientist Louis Brownlow, and the Hoover commissions of 1949 and 1955, chaired by former president Herbert C. Hoover (1874–1964), respectively recommended the creation of the Executive Office of the President (EOP) in order to assist the president’s administration of the federal bureaucracy and an improvement of the relationship between political appointees and top civil servants within the executive branch.

During the 1990s, the widely read and influential book by Vice President Al Gore (b. 1948) called *Reinventing Government* (1993), about his work with the National Performance Review (NPR), explained and advocated the “Third Way” of experimenting with the greater use of nonprofit organizations to provide some public services as an alternative to the extremes of probusiness conservatism and progovernment liberalism. Following the terrorist attacks of September 11, 2001, the federal bureaucracy was expanded to include the Department of Homeland Security and reformed to facilitate greater communication and coordination among federal agencies and between the federal and state governments regarding terrorist-related national security, surveillance, immigration, and transportation safety issues.

PUBLIC ASSISTANCE
At any point in time, some members of an affluent or poor society may be unable to fully support themselves due to a variety of circumstances, including adverse economic conditions (e.g., unemployment), health problems (physical or mental infirmity), changes in family circumstances (e.g., births, deaths, divorce), age factors (e.g., youth, advanced age), and natural disasters. In these situations, the government, in fulfilling its role as enhancer of the well-being of its citizens, may intervene by providing assistance to the affected individuals or families. For the sake of long-term viability, however, it is important to design a system that encourages able-bodied adult public assistance beneficiaries to become self-supporting again. Because public assistance programs seek to provide an economic or social safety net to the disadvantaged or vulnerable members of society, it is not surprising that such programs are subjects of extensive public policy debates in democratic societies. These debates focus on the long-run viability of specific public assistance programs, on distributional impacts, on whether public assistance encourages or discourages job-seeking and childbearing, and on whether or not programs help beneficiaries escape from poverty and welfare dependence, as well as the extent to which governments should be providing such programs.

The governments of the United States, Canada, Japan, and other industrialized countries have developed comprehensive public assistance programs over the years to assist the poor and needy financially or through medical care, employment training, and a variety of other programs. Because of their comprehensive public assistance programs, these countries are labeled welfare states. The sociologists James Rice, Robert Goodin, and Antti Parpo (2006) have articulated some ways in which welfare states contribute to people’s well-being.

THE MEANING OF PUBLIC ASSISTANCE
To many people, public assistance is synonymous with welfare benefits (and because the latter is often perceived negatively, so too is the former). Strictly speaking, public assistance is broader than welfare; it includes cash benefits (e.g., social assistance), direct “in-kind” provision of goods and services (e.g., food stamps, child care services), and tax breaks (e.g., tax credits for families with dependent children). The designation public arises from the fact that some level of government (central, state, or local) controls the relevant financial flows; thus, benefits provided by private charities are not considered public assistance, except in cases where public expenditures are channeled through private charities. Three salient aspects of public assistance programs follow from the above definition. First, the assistance is intended to be provided for the direct benefit of needy individuals or families. Second, because some level of government controls the relevant financial flows, the governments in power influence such expenditures. Third, the benefits, which can be cash, in kind, or in the form of tax breaks, must address some social or economic goal.

Since the 1930s many specialized public assistance programs for low-income households, seniors, youth, the sick and handicapped, and the unemployed have been launched in the United States, in response to changing economic and social conditions. A partial list of such programs includes the Food Stamp Program (FSP), Medicaid, Supplemental Security Income (SSI), Aid to Families with Dependent Children (AFDC), Temporary Assistance to Needy Families (TANF), General Assistance (GA), Job Opportunities and Basic Skills (JOBS), Earned Income Tax Credit (EITC), and the Low Income Home Energy Assistance Plan (LIHEAP). TANF (which replaced AFDC) is what is commonly referred to as welfare; it assists needy families with dependent children, whereas SSI is designed to assist the blind, aged, and disabled. Most of these programs are means-tested (or income-tested)—that is, benefit eligibility is restricted to individuals or households whose income and/or assets are valued below some threshold level. For example, Medicaid provides medical assistance for only certain low-income individuals and households, and FSP ensures provision of adequate nutrition to low-income individuals and households by supplementing their food budget.

According to statistics provided by the U.S. Social Security Administration (2006), in 2002 there were 49.754 million recipients of Medicaid, at a total cost of $213.491 billion; an average of 5.058 million recipients of TANF/AFDC per month, at a total cost of $9.717 billion; an average of 19.094 million recipients of food stamps, at a total cost of $18.257 billion; and 6.940 million recipients of SSI in December 2002, at a cost of $34.567 billion.

ECONOMIC IMPACT OF PUBLIC ASSISTANCE
Public assistance programs are designed to achieve economic and social goals. Two such goals are noteworthy. First, the provision of public assistance is a step toward creating an egalitarian society in which all citizens enjoy a reasonably decent standard of living. Second, public assistance spending may serve as a tool for regulating demand, structuring the labor market, and stabilizing the economy.

Opponents of public assistance programs claim, among other things, that such programs provide disincentives to work and incentives to bear children. These programs also, they assert, divert scarce resources away from productive uses (e.g., investment) to unproductive social services and contribute toward creating a large number of
poor and welfare-dependent individuals and families. These viewpoints have motivated extensive empirical research on the economic and social impacts of specific U.S. public assistance programs. The conclusions of this research have been mixed: For example, case study research by the economist Barbara Wolfe (2002) found that work-effort disincentives exist in both TANF and AFDC. The economists Dean Jolliffe, Craig Gundersen, Laura Tiehen, and Joshua Winicki (2005) examined the impact of FSP on child poverty and found that food stamp benefits lead to large reductions in the poverty gap. The sociologists Taryn Lindhorst and Ronald Mancoske (2006) tracked TANF recipients who were involuntarily removed from welfare rolls, as a result of the increased use of sanctions and time limits on welfare, and identified several negative social and economic effects.

THE U.S. PUBLIC ASSISTANCE RECORD

How does the United States fare relative to other industrialized Organization for Economic Cooperation and Development (OECD) countries in terms of commitment to supporting the standard of living of poor and needy individuals and families? Ideally, comparison should be made on the basis of an examination of the gross (before-tax) total public expenditures on each public assistance program as a ratio of the size of the economy as measured by gross domestic product (GDP), with higher values indicating greater commitment. Although public assistance programs in different countries share the common goal of assisting the poor and needy, there are significant cross-country variations in program design, which makes international comparison problematical. To deal with this problem, the OECD has attempted to create a comprehensive database of internationally comparable data on public social expenditures, which include expenditures on public assistance programs, in the OECD countries. The database focuses on nine social policy areas: namely, old age, survivors, incapacity-related benefits, health, family, active labor market policies, unemployment, housing, and other social policy areas. Because most public assistance programs are means-tested, public expenditures on means-tested programs as percentages of GDP provide a good sense of how levels of public assistance, in particular, compare.

Table 1 shows the gross (before-tax) total public social expenditures and total expenditures on means-tested programs as percentages of GDP for several OECD

countries, as reported by OECD (2007). It is apparent from the table that the United States fares poorly in relation to most industrialized OECD countries, especially the Nordic countries, when gross public social expenditures are considered. In fact, the United States falls below the OECD average for every year between 1990 and 2003. Sweden’s total public social expenditure as a percentage of GDP, which is the highest among the OECD countries for every year between 1990 and 2003, is about twice that of the United States. Another interesting feature of the table is that the total U.S. public social expenditure is very comparable to that of Japan, with both falling below the OECD average. A slightly different story emerges when means-tested programs, which are characteristic of most public assistance programs, are considered. For means-tested programs, the United States and Japan also fall below the OECD average and both countries fare much worse than Australia, Canada, New Zealand, Finland, Ireland, and the United Kingdom.

PUBLIC CHOICE THEORY

Public choice theory is a positive theory of interest group politics that applies the microeconomic perspectives of market exchange to political and policy problems. Borrowing from Anthony Downs’s approach of policy selection (1957), wherein governments select policies to appeal to a winning coalition of voters, public choice theory considers the ways in which interest groups’ policy preferences and relative bargaining power will affect government policies. The theory assumes a logic in which the government awards policy goods to those groups best able to lobby for their interests. Although the public choice method borrows from economics, its principal uses have been in the analysis of political questions. Public choice theory and interest group politics have generally been used in a variety of political contexts, such as tax policy (Becker 1983), trade protection (Schattschneider 1935; Eichengreen 1989), public good provision (Olson 1965), and economic sanctions (Kaempfer and Lowenberg 1992).

According to public choice theory, although a market analogy is a useful way to conceive of policy selection, there remain significant differences between economic exchange markets and political exchange markets. For example, economic market exchanges are generally believed to: (1) be undertaken voluntarily, (2) benefit all those involved, and (3) be Pareto optimal. Political markets, on the other hand, tend to favor one group over others, and are thus distributional and inherently conflictual. Thus, the political market is characterized by competition between opposed interest groups that expend their political capital to secure their preferred policies.

Through this competition over policies between opposed interests, the policy goods ultimately awarded by a government will reflect the influence-weighted preferences of the opposed interest groups. More formally, the political market will equilibrate when the influence-weighted utilities of the stronger groups are equal to the influence-weighted disutilities of their weaker opponents. Furthermore, policy changes will result from shifts in either the underlying distribution of the power of opposed groups or as a result of shifts in the relative salience that groups hold for issues of concern. These shifts will, in...
Public choice theory has two principal variants: the “Chicago School,” which considers the awarding of policy goods through a political market as relatively benign; and the “Virginia School” (based at George Mason University), which is concerned about how competition over government largess undermines social welfare through deadweight costs and inefficiencies. Members of the Chicago School, such as Gary Becker, argue that these social deadweight costs will be minimized for two reasons. First, because the utility of policy goods increases at a diminishing rate (as market distortion and deadweight costs accumulate), winner groups will become decreasingly inclined to lobby for further rents, while loser groups will become increasingly inclined to lobby for relief and a rationalization of the political economy. Secondly, because loser groups lobby to ensure that they suffer the minimum disutilities possible, they will reduce deadweight costs further. As a result, the competition between opposed groups will reduce social costs to a minimum.

On the other hand, members of the Virginia School point out that, because of their political nature, rent transfers are often highly inefficient in order to disguise the extent of the pilfering from the community chest undertaken by beneficiary groups. Worse, when rents are highly concentrated and their costs are widely defused, narrow rent-seeking interests may be able to exploit collective action problems on behalf of the larger body politic for their own benefit, resulting in further net social and economic inefficiencies. For example, the economist Gordon Tullock notes that farm support is often given through inefficient market manipulation, as opposed to more efficient cash subsidies, in order to conceal the real scope of the super-normal returns to farming interests through the political process (1989). Thus, due to their concern with the interaction between interest group pressures and rent-seeking and governments’ proclivity for overregulation, the Virginia School is pessimistic with respect to interest groups’ normative impact on policy outcomes.

Although public choice theory and interest group politics have been used with some success in the political economy and economics literatures, critics have noted two potentially significant problems with this body of work. First, public choice theory may give short shrift to the key role that domestic institutions play in determining policy outcomes, because the groups of interest are often modeled as if they were operating in an institutionally unconstrained policy market. Yet while work in the public choice tradition often does not explicitly address institutions, they can still be incorporated into such a framework. As politically determined rule- and agenda-setting mechanisms, institutions are amenable to the same lobbying and bargaining processes described above. That is, by thinking of institutions as meta-policies, public choice tools can be used to endogenously analyze institutions’ creation and downstream effects.

Second, critics allege that public choice theory, which was developed primarily within the American political context, is unsuited to nondemocratic countries in which the capacity of opposition groups to lobby for their policy preferences is repressed. It is important to note that the metaphor of “lobbying” need not be taken literally, however. As conceived of in public choice theory, lobbying can refer to any kind of influence. Regardless of the type of regime, political bargaining always takes place, even if it is only implicit. Although the preferences of excluded groups in nondemocratic countries may not affect the political process directly, they may do so indirectly, since disenfranchised groups can signal their policy preferences by engaging in acts of political resistance such as fomenting armed rebellion. This resistance, or the threat of it, effectively acts as a tax on the ruling group’s willingness and ability to unilaterally set policy because it raises the costs of enforcement and administration. Thus, even in nondemocratic states, policies will be determined through a bargaining process between opposed groups, although ruling groups in authoritarian regimes are, of course, likely to enjoy policies far closer to their preferences. In these regimes there is an extreme concentration of political capital, in contrast to its relative diffusion within democratic regimes.

PUBLIC GOODS

Public goods such as law enforcement, national defense, highways, and environmental regulation are typically provided by governments rather than the private sector, although this is not a requirement. Governments provide these because public goods share two properties that make their provision by private firms difficult. The first is that there is no rivalry in their consumption: Use of a public good by one individual does not decrease its value to others. The second is that the benefits are freely accessible to all, so no individual can be excluded from the use of these goods.

The first condition implies that financing production by charging a price for access to the good would inefficiently restrict access to the good. The second condition of non-excludability implies that charging a price is also infeasible from a practical standpoint (Figure 1). As a result, private firms will generally have little incentive to produce public goods: Provision requires collective action among those parties desiring the good (Olson 1965). Insufficient financing for production is likely to result from voluntary contributions, however, since individuals need not pay a price to enjoy an open-access public good. This has been called the free-rider problem. As a result, provision of public goods generally falls to governments, which have the coercive power necessary to levy the taxes required to pay for the goods.

A difficulty arises, however, in establishing both equity and the preferred level of a public good. To provide the sufficient level of a public good, governments must know how much individuals benefit from it. Optimally, an individual’s tax assessment would then reflect his or her own valuation of the public good. In practice, however, when individuals know they cannot be denied access to the good and will be assessed taxes in proportion to their announced valuation, they have no incentive to reveal their true preferences (the free-rider problem again). Economists have studied various means by which governments can induce individuals to provide information about their preferences. The key to these revelation mechanisms is that the taxes levied on the individual to finance the good must be set independently of their announced valuation.

This fact, combined with the fixed costs of designing a tax system, provides one explanation for the observation that countries typically organize so that a single government provides multiple public goods, rather than having a system of overlapping jurisdictions each responsible for a single public good. Not all public goods are most efficiently provided by a single centralized authority, however, and a hierarchy of jurisdictions and subjurisdictions may exist for providing public goods. One example is the U.S. system of federal, state, and local governments, in which the federal government provides military defense, regulates commerce, and designs social welfare programs to achieve equity goals, while state governments set regulations on social behavior and local governments provide a range of services from education to street cleaning. Another example is the hierarchy between public goods provided within sovereign nation-states and global public goods that must be provided through collective action among a group of nation-states, such as peacekeeping, international regulation of civil aviation and commerce, exchange rate management, and efforts to combat global warming.

Analytically, the key distinction between global, national, and state or local public goods rests on two dimensions: the sovereignty of the nation-state and the mobility of the citizenry. The free-rider problem can be overcome in providing public goods at the level of the nation-state and its subjurisdictions through the coercive power of governments to enforce tax and regulatory policies, but no similar mechanism exists for the provision of global public goods. Similarly, within the nation-state, citizens are typically free to live in the subjurisdiction that offers their preferred combination of public-good provision and tax burden. As a result, efficient provision can be achieved by citizens “voting with their feet” (Tiebout 1956). Migration between nation-states is more difficult, however, and between planets impossible, so the political process by which national and global public goods are determined is crucial.

Ideally, responsibility for public goods should be allocated among the hierarchy of governments using several criteria: (1) the extent of nonrivalry (including both the proportion of fixed costs relative to variable costs and the geographic scope of the benefits); (2) the uniformity of
opinion regarding the preferred nature of the public good; and (3) problems of adverse selection. Public goods that entail relatively high fixed costs and have widespread benefits, such as maintaining peace and security through law enforcement and the military, or maintaining clean air and water and a stable climate through environmental protection, should optimally be provided at a centralized level (Figure 2). Where preferences over the size, quality, or nature of the public good vary widely, however, more decentralized provision may be preferable. This is particularly true for goods that have more limited geographic benefits, and thus a higher degree of rivalry, such as public education and community social activities. Wallace Oates (1972) argues further that policies designed to achieve distributional equity goals are also best provided at a federal level to avoid the adverse budgetary effects that might arise with poorer families selecting to live in, and richer families selecting to live outside of, those state and local jurisdictions with more progressive policies.

It is worth noting that not all publicly provided goods are pure public goods by the conventional definition employed in this entry. Information, for instance, is nonrival in consumption but certainly potentially excludable. Legal rights and the rule of law are potentially excludable as well, as history has demonstrated to many disenfranchised communities. Common property resources like fish, on the other hand, are nonexcludable, but their consumption is rival. In each case government regulation of the provision process—whether through patent law, civil rights legislation, or fishery management—can in principle be desirable. In weak and failed states, however, regulation of resources may generate incentives for corruption, as officials “sell” licenses and grant access for personal profit. In other cases, governments have opted to provide private goods, such as education, health care, or postal services, all of which are both rival and excludable, in order to capitalize on fixed costs, achieve beneficial externalities, or to adopt certain standards (the benefits of which are both nonrival and nonexcludable).

PUBLIC HEALTH

Public health is a branch of the social and health sciences, as well as a field of social and health endeavor, that aims at collective action for the prevention of disease and the promotion of health. The U.S. Institute of Medicine offers this definition: “public health is what we, as a society, do collectively to assure the conditions in which people can be healthy” (K. Gebbie, L. Rosenstock, and L. M. Hernandez 2003). Depending on the political philosophy of governance and the role of the state, this aim and its operational applications have taken different shapes in different contexts. In some contexts, “public health” refers to public-sector health; in other contexts, the term refers to the public’s health.

Public health is as old as history itself. Most holy texts (including the Bible, Torah, and Qur’an) contain instructions regulating sanitary behavior. Other belief systems, such as the Indian Ayurveda (from the Sanskrit ayu—life and veda—knowledge of), have formulated prescriptions for leading healthy lives. The Hippocratic writings have been highly influential in Western conceptualizations of health and illness. Although the ancient Greek physician Hippocrates (c. 460–377 BCE) and his school are found to be the fathers (and mothers) of modern medicine, their instructions for healthy housing are the direct forebears of current perspectives on environmental health.

The rise of modern public health occurred in the mid-nineteenth century. With the advance of statistics and empirically-based science, health advocates (later known as the hygienists) in France, Germany, England, and the United States endeavored to link disease patterns to environmental conditions. These hygienists had roots
in engineering, law, and charity, and to a lesser extent in emerging scientific—allopathic—medicine. British royal anesthesiologist John Snow (1813–1858) made a breakthrough in 1854. Using an ancestor of what is known as a geographic information system, Snow was able to attribute cholera outbreaks in Victorian London to the quality of water coming from the city’s Broad Street pump.

Although public health science had certainly made its mark with the work of early epidemiologists, public health action was relatively slow to follow, mostly because the proposed interventions met with considerable political resistance. The idea that large infrastructural works (sewage systems, garbage collection, piped water) had to be put in place for the public good was persistently countered with arguments that the delivery of appropriate individual health care services, and emphasis on the responsibilities of individuals for their lifestyles, would yield better results. Ultimately, though, the political argument that the workforce was withering as a result of lack of public action won over the critics.

Formal public health training in this tradition started at the Massachusetts Institute of Technology in 1889 and at the London School of Hygiene and Tropical Medicine in 1899. A pressing debate emerged in the United States around the question of whether public health was a branch of medicine and should thus be taught in medical schools. The Flexner Report (1910), sponsored by the Carnegie Foundation, found that schools of public health should be separate entities. In Europe, however, there was a commonly shared belief that public health was an integral part of the medical realm. Outside the United States, the Rockefeller Foundation eventually sponsored schools of public health that were closely allied with medicine (in Zagreb, Beijing, and London). Public health in Europe became known as social medicine or (in the United Kingdom) as public health medicine.

The breakthrough stature that the field had acquired in the second half of the nineteenth century withered, regrettably, as a consequence of advances in vaccine development and immunology. The dominant idea became that most, if not all, disease could be treated or prevented through immunological interventions. Public health could contribute to this notion by developing population-based vaccination campaigns. The social and political aspects of public health science and action lost prominence, even in those realms where the political dimensions of health issues were blatantly obvious. Governments had been engaging, since a failed first meeting in Paris in 1851, in a series of “sanitary conferences” aimed at regulating the transmission of disease between nation-states through measures such as quarantine. Such efforts would clearly have had an impact on trade, which was why most of these conferences had limited success.

In the era of globalization, little has changed in the public health landscape. Trade and mobility are profound drivers of the potentially rapid spread of infectious diseases such as avian influenza or SARS (severe acute respiratory syndrome)—the 2003 SARS outbreak in China led to a World Health Organization (WHO) travel warning for Toronto—and tensions between individual foci on the promotion of health and community-based orientations have not been resolved.

One would, for instance, expect that modern public health knowledge and practices would have been able to prevent the Black Death (or “pestilence”) that ravaged Europe in the mid-fourteenth century. At the time, witchcraft, ethnicity (arguments reminiscent of those voiced in the twentieth century on the HIV/AIDS epidemic by some religious groups), and seasonal bad airs were blamed for the pandemic. Current scientific knowledge of the disease pathogen and its vectors would, supposedly, account for more effective interventions, reducing overall mortality. This supposition is only partly true. Bubonic plague is still endemic in many nations. Similarly, the global community has not been able to fully contain or control contemporary cholera pandemics, nor will it be able to fully prevent annual influenza outbreaks, including those caused by particularly virulent pathogens such as the H1N5 avian influenza virus. It must be recognized that pathogens are an inseparable element of the global ecosystem, and global public health surveillance and control systems—partly due to political indolence, sometimes referred to as a “betrayal of trust”—have only a limited capacity to proactively engage in their complete prevention.

Many international organizations include health in their considerations: for example, the International Labor Organization (ILO) deals with workplace health, UNICEF with maternal and child health, the UN-Habitat with urban health, and UNESCO with education for health in schools. The United Nations technical agency responsible for health matters since its inception in 1948 (its establishment urged by Brazil and China at the UN founding conference in San Francisco in 1945) is the WHO.

The WHO is the only UN technical agency that, apart from a global headquarters and national liaison offices, has six Regional Offices (in Europe, the eastern Mediterranean, Africa, Southeast Asia, the Western Pacific, and the Americas). These offices formulate “regional” policies following directions from the global World Health Assembly. The programs of the WHO in its first decades focused on infectious disease. The greatest accomplishment of this era is the first and only eradication of a major human disease, smallpox (1967–1977). This accomplishment also signaled, however, the end of the infectious disease paradigm. From the launch of the
“primary health care” approach following an international meeting in Alma Ata (Almaty), Kazakhstan, in 1978, the community and social aspects of health promotion and the management and delivery of care became more important than biomedical intervention considerations. In this shift, the WHO has experienced great successes and failures. Under the visionary leadership of Halfdan Mahler (1973–1988), the WHO positioned itself as a powerful broker for health between professionals, governments, and communities. The WHO’s next director-general, Hiroshi Nakajima (1988–1998), was accused of letting the organization fall victim to corruption, a pawn of (pharmaceutical) industries, with an ineffective bureaucracy not responsive to such global threats as HIV/AIDS nor the call for evidence-based medicine and public health. His successor, Gro Harlem Brundtland (1998–2003), was elected to take charge and reposition the organization. One of her most visible accomplishments was the commissioning of a series of studies into macroeconomics and health chaired by the American economist Jeffrey Sachs. Lee Jong-Wook (1945–2006), who became WHO director-general in 2003, further advanced the social science angle of the organization by appointing in 2005 a prestigious Commission on Social Determinants of Health. This commission is to report on early child development, health systems, employment, globalization, urban settings, and gender in public health, among other issues. This range of topics again emphasizes the intrinsically political nature of public health.

In the 1990s, the WHO established a list of essential functions to which public health agencies should strive to conform:

- Prevention, surveillance, and control of communicable and noncommunicable diseases
- Monitoring of health situations
- Health promotion
- Occupational health
- Protection of the environment
- Public health legislation and regulations
- Public health management
- Specific public health services
- Personal health care for vulnerable and high-risk populations

The list reflects the ideal that public health must embrace insights from the social and natural sciences. These would range, for instance, from molecular medicine to empowerment and community development, toxicology, and political science. Some disciplines, such as epidemiology and health services research, are uniquely aligned to the public health realm. Others have specialized branches related to public health, notably biostatistics, health economics, sociology, anthropology, psychology, and environmental health. In many universities, schools of public health provide a critical link between faculties. However, the domain is also rich in contention, particularly where the survival or growth of “established” disciplines is concerned. A pivotal review by the U.S. Institute of Medicine, for instance, demonstrated the enormous untapped potential for insights from the social and behavioral sciences in the promotion of health. These insights, for reasons linked to “disciplinary exclusiveness,” have not yet pervaded “traditional” public health research and teaching.

Another level of rivalry has developed around the application of public health expertise. On a scale, two extremes are found. One, predominantly carried by laboratory-based public health sciences, poses that clinical expertise determines courses of action. This would, for instance, relate to the legitimacy to implement population-wide vaccination or risk-behavior-change campaigns (top-down). Others, notably the radical social sciences, start from the position that health is an inherently social condition and that community-driven action is most appropriate (bottom-up). Agreement is difficult to reach, and a “mixed-scanning” approach is often advocated by the WHO and many local public health agencies.

An organization strongly committed to the bottom-up approach is the global People’s Health Assembly (PHA), an alliance of academics, communities, and nongovernmental organizations. The PHA endeavors to balance the expert-driven globalized stance with a community-based local (“glocal”) approach. A major imbalance with which both the PHA and the WHO struggle is the “ninety/ten divide”: 90 percent of the global public health research effort is spent on only 10 percent of the global health burden. Important players in this arena, apart from the WHO, are private sector entities. These include pharmaceutical industries and charitable organizations such as the Bill and Melinda Gates Foundation (the largest single donor to public health efforts—over $5 billion—in 2005).

The nexus between globalization and health is an important research challenge. Like the unresolved ninety/ten divide, most public health research resources are devoted to issues in industrialized nations. These include such matters as access to and the efficiency of health services—for example, medical technology assessment and health services financing schemes (often mirroring, again, the difference between public sector or the public’s health). A critical issue in these analyses is the inequitable distribution of access, as well as disease burden, within and not between nations. Research into equity and inequalities in health top many European
agendas; in other countries, such terms have been deemed politically taboo, which has not prevented research into areas that are alternatively labeled with less value-laden terms, such as social exclusion or diversity and health. Ethnicity, socioeconomic status, heredity, and gender issues thus remain at the core of many public health controversies.

PUBLIC INTELLECTUALS
SEE Intellectuals, Public.

PUBLIC INTEREST
While there is no one public interest, most political philosophers credit some notion of collective welfare. Examples include French philosopher Jean-Jacques Rousseau’s “general will,” U.S. president James Madison’s “collective good,” or English philosopher Jeremy Bentham’s “greatest good for the greatest number.” In debate, public interest is often invoked when a faction’s influence harms the larger group. As James Madison defined it in Federalist Paper number 10, the tenth Federalist Paper in a series of published articles arguing for the ratification of the U.S. Constitution:

By a faction, I understand a number of citizens, whether amounting to a majority or a minority…united and actuated by some common impulse of passion, or of interest, adverse to the rights of other citizens, or to the permanent and aggregate interests of the community.

There are two core conceptions of the public interest, organic/republican and utilitarian/liberal. In Western philosophy, “republican” societies regard the state or society as a collective entity, possessing virtues and commanding citizen obligations that dominate individual or self-interested objectives. “Liberal” conceptions of public interest focus on individual welfare or value, and invoke some assumption justifying interpersonal comparisons of value or satisfaction.

Political theorists couple normative conceptions of public interest with claims about institutional design. One extreme is the Rousseau-Marx approach (named after Rousseau and German political philosopher Karl Marx), which suggests an objective underlying definition of the good or virtuous society. According to this approach, any action or policy that violates this objective “public interest” is a mistake, or even a crime against citizens.

Near the other extreme are conceptions of the public interest that credit consensus, appealing not to objective values but to deliberation. In varying degrees this view is embodied in the writings of John Rawls, Jürgen Habermas, and James Fishkin. This approach claims that reasonable people can achieve consensus (or near consensus) on public policy problems through deliberation.

But some would go further. “Agonistic pluralists,” such as Chantal Mouffe, require only that citizens disagree peacefully. Policy debates, in this view, are value-laden and emotional, so requiring consensus causes violence. The democratic process is the alternative to violence, an arena in which fundamental differences can be aired and discussed, preventing difference from hardening into enmity and violence. In this regard, it is participation and democratic engagement, in and of itself, that is the public interest.

RATIONAL CHOICE THEORY
Another approach, rational choice theory, is consequentialist and utilitarian. The public interest can only be defined, in this tradition, in terms of the Pareto criterion. The Pareto principle is essentially unanimity: Given a status quo policy A, new policy B serves the public interest if, but only if, all members of the society prefer B to A. A weaker comparison would allow that many citizens are indifferent between A and B, but at least one prefers B to A, and none prefer A to B.

Other proponents might extend valid public interest arguments to include the work of welfare economists John Hicks and Nicholas Kaldor. Their “compensation,” or “potential Pareto” principle, defines the public interest in terms of monetized gains and losses. If some citizens prefer new policy B to status quo A, but others prefer A to B, then the Pareto criterion does not apply. But the policy authority can still discover the public interest, adding up
the gains (how much would those who prefer B sacrifice to effect the change?) and the losses (how much would those who prefer the status quo offer to block the change?). If the summed gains exceed the summed losses, then the gainers can compensate the losers and still leave some surplus. Disagreement becomes unanimity.

Cost-benefit analysis uses this reasoning to derive the public interest. So does the use of eminent domain, which governments use to take private property in the public interest. The difference is that compensation must be paid in the case of eminent domain, where no compensation is needed in a cost-benefit analysis. Both procedures are as close as we can get to implementing Bentham’s “greatest good for the greatest number.”

PUBLIC CHOICE THEORY
Public choice theory is a strand of rational choice that makes two more assumptions about the formulation of the public interest. First, the public interest is defined in utilitarian terms. Second, all participants, including public officials, pursue their perception of their private interest. But the public officials respond to incentives created by institutions.

For example elected officials must seek reelection, and therefore serve voters, though out of self-interest, not love for the voters. Institutional design is the key to creating this coincidence of public interest and private action of officials. In Federalist Paper number 51 the authors wrote, “Ambition must be made to counteract ambition.” A federal system, with separation of powers, reasoned Madison and coauthor Alexander Hamilton in this essay, transforms private interest to coincide with the public interest.

Kenneth Arrow’s famous “Impossibility Theorem,” introduced in his 1963 book Social Choice and Individual Values illustrates a problem with any specification of public interest in terms of individual preference “lists.” Arrow’s result, which shows that only dictatorship satisfies the other normative criteria he specifies for ethically defensible government, raises important questions about the coherence of democracy as a means of discovering the public interest. But since the Arrow argument affects only disaggregated utilitarian conceptions of the public interest, organic conceptions might still be defended on some other grounds.

An alternative approach to public choice theory is to begin with the psychological determinants of citizen conceptions of the public good, and to build upon this foundation a more psychologically oriented theory of the actions of public officials based on conceptions of community and the obligations of health professionals to serve the public interest. This view can be found in a large number of different public health disciplines, but it is most coherently developed in community psychology, as outlined in Julian Rappaport’s 1977 book Community Psychology: Values, Research, and Action. Some psychologists practicing “critical community psychology” argue that much preventable human suffering can be traced to policies and institutions that violate and suppress the public interest. Treatment individual psychopathologies, in this view, is a red herring. The only effective “treatment” is to work for social justice, ameliorating disparities and transforming institutions to make such disparities less likely to reappear. Thus, knowledge of the public interest imposes an obligation on health professionals to work outside of their narrow specialties toward social change.

How might one tell if a policy serves the public interest, an official’s private interest, an organized group’s interest, or something else? The answer is contingent on many things, as Arthur Denzau and Michael Munger showed in their 1986 article “Legislators and Interest Groups: How Unorganized Interests Get Represented.” The essential responsiveness of a political system to the public interest depends on legislator goals, agency professionalism, the private influence of organized groups, and the competitiveness of the electoral system. But public interest also is contingent on citizens’ sophistication. If citizens know their private interests, and understand how policies affect those interests, then competitive elections push policy close to the public interest, at least in utilitarian terms. But if citizens do not understand their private interests, or if complex policies are misunderstood or misrepresented in public discourse, or even if elections are not competitive due to campaign finance or party organization barriers, public policy will diverge sharply from the public interest in favor of policies favored by narrow special interests.

Public Interest Advocacy

Public Interest Advocacy is performed by organizations that exist primarily to promote a common good that extends beyond the narrow economic or sectarian goals of their members or supporters. Organizations in this domain typically address such issues as consumer protection, free markets, the environment, taxation, peace, fiscal responsibility, campaign finance reform, civil rights, and social welfare. Prominent examples include the American Civil Liberties Union, the Center for Science in the Public Interest, Common Cause, the National Taxpayers Union, the Natural Resources Defense Council, Peace Action, and Public Citizen. Public interest advocacy groups make up less than 5 percent of the total interest-group universe in Washington, D.C., which is heavily dominated by corporations, business associations, and occupational groups. Public interest groups are disproportionately visible, however, allowing them to draw more attention from the media and spots at congressional hearings than their numbers alone would suggest.

A precise delineation of which organizations are engaged in public interest advocacy is difficult to establish. First, the term “public interest” is fundamentally ambiguous. One person’s public interest may be another person’s special interest, and vice versa. All organizations have an incentive to frame their concerns in terms of the public interest, even if they are motivated principally by private interests. Second, economic interests are increasingly using the facade of public interest advocacy to conceal their private political agendas from the public. For example, in the late 1990s, the pharmaceutical industry established “Citizens for Better Medicare” as a front organization to stop the enactment of prescription drug legislation that would have been adverse to its economic interests. Third, many traditional public interest advocacy organizations are assembling portfolios and boards of directors that bear closer resemblance to the for-profit sector than to the not-for-profit sector. As a result, classifying a group as a public interest advocacy organization requires probing beneath the surface of its stated mission and goals to discover its sources of financial and political support.

Ambiguities of classification aside, public interest advocacy organizations play a major role in representing otherwise neglected constituencies. They are often able to overcome the free-rider problems inherent in the provision of collective goods by offering selective incentives for individuals to contribute to their organizations, by using informal pressures distributed through decentralized social networks, by attracting generous patrons, and by latching on to new areas of government involvement. Their tactics include lobbying, testifying at congressional hearings, submitting regulatory comments, mobilizing grassroots constituents with public rallies and letter-writing campaigns, buying media advertising, filing amicus curiae briefs with appellate courts, and sponsoring class-action or other lawsuits. They most readily influence public policy when they raise new issues on the public agenda, establish reputations as experts on policy issues, demonstrate the ability to reliably mobilize constituencies important to politicians, become connected as key brokers within issue networks, or reframe issues to change a debate in favor of their concerns.

Public interest advocacy has had a major impact on the formulation of environmental legislation, such as the Clean Air Act Amendments of 1970, which made uniform national emissions standards a goal of national public policy. More recently, public interest advocacy was instrumental in passing the Bipartisan Campaign Reform Act of 2002, which banned unlimited “soft money” contributions to national political parties. These campaigns benefited from the charismatic leadership of political entrepreneurs such as Ralph Nader, who founded (or helped to found) more than a dozen public interest advocacy organizations (such as Public Citizen and the Public Interest Research Groups) over the course of his lifetime.

The dramatic rise of public interest advocacy organizations, following largely from the mass social movements of the 1960s and 1970s, has significant implications for the nature of civil society in the United States. First, their rise reflects, and helps to drive, a shift in advocacy away

**PUBLIC INTEREST ADVOCACY**

Public interest advocacy is performed by organizations that exist primarily to promote a common good that extends beyond the narrow economic or sectarian goals of their members or supporters. Organizations in this domain typically address such issues as consumer protection, free markets, the environment, taxation, peace, fiscal responsibility, campaign finance reform, civil rights, and social welfare. Prominent examples include the American Civil Liberties Union, the Center for Science in the Public Interest, Common Cause, the National Taxpayers Union, the Natural Resources Defense Council, Peace Action, and Public Citizen. Public interest advocacy groups make up less than 5 percent of the total interest-group universe in Washington, D.C., which is heavily dominated by corporations, business associations, and occupational groups. Public interest groups are disproportionately visible, however, allowing them to draw more attention from the media and spots at congressional hearings than their numbers alone would suggest.

A precise delineation of which organizations are engaged in public interest advocacy is difficult to establish. First, the term “public interest” is fundamentally ambiguous. One person’s public interest may be another person’s special interest, and vice versa. All organizations have an incentive to frame their concerns in terms of the public interest, even if they are motivated principally by private interests. Second, economic interests are increasingly using the facade of public interest advocacy to conceal their private political agendas from the public. For example, in the late 1990s, the pharmaceutical industry established “Citizens for Better Medicare” as a front organization to stop the enactment of prescription drug legislation that would have been adverse to its economic interests. Third, many traditional public interest advocacy organizations are assembling portfolios and boards of directors that bear closer resemblance to the for-profit sector than to the not-for-profit sector. As a result, classifying a group as a public interest advocacy organization requires probing beneath the surface of its stated mission and goals to discover its sources of financial and political support.

Ambiguities of classification aside, public interest advocacy organizations play a major role in representing otherwise neglected constituencies. They are often able to overcome the free-rider problems inherent in the provision of collective goods by offering selective incentives for individuals to contribute to their organizations, by using informal pressures distributed through decentralized social networks, by attracting generous patrons, and by latching on to new areas of government involvement. Their tactics include lobbying, testifying at congressional hearings, submitting regulatory comments, mobilizing grassroots constituents with public rallies and letter-writing campaigns, buying media advertising, filing amicus curiae briefs with appellate courts, and sponsoring class-action or other lawsuits. They most readily influence public policy when they raise new issues on the public agenda, establish reputations as experts on policy issues, demonstrate the ability to reliably mobilize constituencies important to politicians, become connected as key brokers within issue networks, or reframe issues to change a debate in favor of their concerns.

Public interest advocacy has had a major impact on the formulation of environmental legislation, such as the Clean Air Act Amendments of 1970, which made uniform national emissions standards a goal of national public policy. More recently, public interest advocacy was instrumental in passing the Bipartisan Campaign Reform Act of 2002, which banned unlimited “soft money” contributions to national political parties. These campaigns benefited from the charismatic leadership of political entrepreneurs such as Ralph Nader, who founded (or helped to found) more than a dozen public interest advocacy organizations (such as Public Citizen and the Public Interest Research Groups) over the course of his lifetime.

The dramatic rise of public interest advocacy organizations, following largely from the mass social movements of the 1960s and 1970s, has significant implications for the nature of civil society in the United States. First, their rise reflects, and helps to drive, a shift in advocacy away...
from material concerns (such as rising wages) toward post-material concerns (such as environmentalism). Second, their growth leads to a shift away from organizations based on the active participation of their members and toward organizations that rely on their members only to pay dues or provide financial support (“checkbook” members). Because these organizations are generally managed by paid, middle-class professionals rather than by citizen-activists, they may mute efforts toward genuine civic engagement.

Political pressures sometimes undermine the willingness of organizations to engage in public interest advocacy. Not-for-profit organizations are often discouraged from undertaking advocacy efforts because of concerns about losing their tax-exempt status under federal law. Not-for-profit organizations are permitted to engage in lobbying if it is not a “substantial” part of their activities. However, lack of clarity about how much activity meets the substantial threshold leads many not-for-profit executives to worry that the Internal Revenue Service could construe any level of political activity as a violation of the law. As a result, the not-for-profit sector as a whole pursues less public interest advocacy than is permissible under current law.

The range of public interest advocacy is limited not only by the external political pressures on an organization but also by its internal political dynamics. Advocacy organizations frequently do not represent all the constituencies within their purview equally. Leaders are more likely to direct their attention to the concerns of advantaged subgroups within their memberships in lieu of working on issues important to disadvantaged subgroups. When working on advantaged-subgroup issues, leaders tend to frame the issues as if they affect the majority of the organization’s constituents, even if the advantaged subgroup in fact is a minority. Conversely, when talking about disadvantaged-subgroup issues, leaders tend to frame the issues as if they affect a minority within the organization, no matter how large the actual population. The consequence of these tendencies is that groups that are intersectionally marginalized—that is, they have more than one marginalized status, such as black women—are the least represented by public interest advocacy organizations.

The increasingly partisan nature of American politics leaves the future of public interest advocacy organizations in question. The more that all advocacy is viewed as following from predetermined partisan or ideological points of view, the harder it is for some observers to accept that any organization legitimately advocates for an unbiased public interest. While the number of public interest advocacy organizations continues to grow robustly, the general political environment surrounding them threatens to reduce their relevance.

**PUBLIC OPINION**

In democratic societies, governments are widely expected to respond to citizens’ preferences. This implies that an accurate process for measuring these preferences exists. However, the capacity to measure public opinion scientif-
ically was not developed until the twentieth century. Modern polling techniques have greatly expanded the ability of government officials to measure public opinion, including opinions of subgroups in society, and to act accordingly in their decision making. Public opinion is frequently measured today, and it has wide-ranging applications in business, academic settings, politics, and policymaking.

DEFINITION AND SCOPE OF PUBLIC OPINION

The political scientists Robert Erikson and Kent Tedin define public opinion as "the preferences of the adult population on matters of relevance to government" (2005, p. 6). However, in early American history, public officials conceived of public opinion primarily as the attitudes of the most educated, affluent subgroup of white males, who were also in the best position to convey their views to officials. The expansion of voting rights nationwide—first to white males who did not own property, (1830s), and then to women (1920), to African Americans (1965) and finally to those from eighteen to twenty-one years of age (1971)—forced public officials to broaden their conception of whose opinions deserved their attention. In addition, the United States' population continues to grow, with much of this growth coming from immigration.

These developments mean that pollsters face the mounting challenge of measuring opinions from a sample that accurately reflects an ever-growing, ever-changing population. The influx of immigrants sometimes raises language barriers to pollsters (although some pollsters use Spanish-speaking interviewers), and new technologies (such as answering machines, "caller ID" boxes, and cellular phones) are creating new barriers to pollsters' reaching survey respondents by telephone, the preferred method.

THE HISTORY OF THE MEASUREMENT OF PUBLIC OPINION

Before and during the nineteenth century, there were very few systematic methods for measuring public opinion. The best nineteenth-century method available, the straw poll, was conducted by magazines and newspapers, which asked readers to send in a response ballot. Most straw polls centered on predicting presidential elections. For example, in 1896 the Chicago Record conducted an elaborate and expensive straw poll to predict the outcome of the hard-fought presidential election between William McKinley and William Jennings Bryan. However, some straw polls sought to measure issue preferences, especially in the 1920s, when they were used to measure attitudes about the emotional issue of Prohibition.

Straw polling was necessarily haphazard and informal, only capturing opinions of those who read such publications—generally the most affluent and educated. They were of very limited use, then, in gauging opinions of American adults generally. The upper-class bias in straw polls had serious consequences during the 1936 presidential election between Franklin D. Roosevelt and Alf Landon. That year, Literary Digest magazine sponsored a nationwide straw poll using respondents whose names were drawn from telephone directories and automobile registration lists. The Literary Digest poll predicted that Landon, the Republican candidate, would win the presidential election, 57 percent to 43 percent. Instead, Roosevelt swept to a landslide re-election, winning 62.5 percent of the popular vote. The fatal flaw of the Literary Digest poll was that its respondents were on average much more wealthy than the average American. During the Great Depression, the affluent were heavily Republican, but they were greatly outnumbered by the less affluent, who voted resoundingly Democratic, thus ensuring Roosevelt's victory. The Literary Digest polling fiasco was a major contributor to the magazine's bankruptcy in 1938.

THE DEVELOPMENT OF SCIENTIFIC OPINION POLLING

While 1936 sounded the death knell for straw polling, it also marked the advent of a new era of scientific polling. In 1936, three younger pollsters with market-research backgrounds, Archibald Crossley, Elmo Roper, and George Gallup, also conducted polls to predict the presidential election. Though still 7 percent off the mark, they fared far better, predicting that Roosevelt would win 56 percent of the popular vote. All three pollsters would go on to found their own polling organizations, with the Gallup Poll the most famous of them. Gallup introduced important new methods in polling, including use of in-person interviews and adopting "quotas" to ensure that samples of respondents reflected social and economic characteristics of the larger population. For example, if the national population were 49 percent male, 17 percent African American, 68 percent Protestant, and so on, Gallup would strive to ensure that his respondent pools reflected similar proportions.

This "quota sampling" technique would soon prove problematic itself, however. In 1940 and 1944, Gallup's polls accurately predicted presidential election results, but each time they overestimated the Republican vote. In 1948 the Gallup Poll predicted that the Republican candidate for president, Governor Thomas Dewey of New York, would defeat the incumbent, President Harry S. Truman, by a margin of 49.5 percent to 44.5 percent. The Crossley and Roper polls also predicted Truman's defeat, by even wider margins. But after a surge in support dur-
ing the campaign’s final week, Truman emerged victorious. Analyses of the failings of the 1948 polls centered on the use of quota sampling, which under-represented social and economic groups more likely to favor Democrats. After 1948, pollsters abandoned quota sampling in favor of probability sampling, which uses random sampling techniques to select communities, neighborhoods, households, and eventually adult individuals, such that all have equal probabilities of being contacted by the pollster. Although not perfect, probability sampling remains the best method pollsters have of generating samples of poll respondents that accurately reflect the larger population of American adults.

THE ADVENT AND GROWTH OF ACADEMIC POLLING

George Gallup and his contemporaries Roper and Crossley were commercial pollsters, concerned with profitability. During the 1940s, academic researchers, especially social scientists, realized the importance of polling for research purposes as well. In 1941 the National Opinion Research Center (NORC) was founded at the University of Chicago, and in 1946 a group of scholars founded the Survey Research Center (SRC) at the University of Michigan. Authors affiliated with both the NORC and SRC would soon produce major studies using nationwide surveys conducted by these organizations. The most important of these was *The American Voter* (1960), a prolific study of American public opinion and voting by the political scientists Angus Campbell, Philip Converse, Warren Miller, and Donald Stokes. Both NORC and SRC continue to sponsor large nationwide surveys every election year, and the results of these surveys are widely used by pollsters, government officials, journalists, and political scientists. The SRC, along with the University of Michigan’s Center for Political Studies, has conducted the American National Election Studies (ANES) every even-numbered year since 1948. Other important academic-based surveys include the NORC-sponsored General Social Survey (GSS), which has occurred annually or biannually since 1971.

Both the ANES and GSS rely on in-person interviewing, which is extremely expensive. The ANES typically interviews respondents both before and after presidential elections, asking hundreds of questions, with total interviewing times of three hours or more. Academic polls typically devote considerable time and resources to accurate sampling, clear question wording, and thorough reporting of results. Most poll questions yield closed-ended, fixed-format responses (such as agree/disagree, a 7-point scale, or even a 100-point scale), which produce results that can be expressed in numbers and subjected to statistical analysis. This emphasis on quantification is virtually universal in academic polling today, and it is also common in commercial polling, including the market research studies businesses commonly use to identify new markets or measure customer satisfaction, among other things.

The mass media, too, are now heavily involved in polling. Because of the fast pace of politics, media organizations frequently sponsor surveys to measure opinions on important issues of the day. During election campaigns, media-sponsored tracking polls (“if the election were held today, who would you vote for?”) are common also. Major media organizations that often commission nationwide surveys include the *New York Times*, which often partners with CBS News, and the *Washington Post*, which often partners with ABC News. Most media-sponsored surveys are conducted by telephone because of the high costs and large investments of time that in-person interviews require.

THE INTERNATIONAL SCOPE OF PUBLIC OPINION RESEARCH

Public opinion polling is not uniquely American, though many modern polling techniques were introduced and refined by Americans. Polling is big business worldwide, with both commercial and academic polling organizations easy to find in industrialized democracies. In less developed nations, polling organizations are less common, though citizens in Asia, Africa, and Latin America are increasingly sought after by pollsters. For example, the University of Iowa political scientists Arthur Miller and Vicki Hesli have directed surveys measuring Russian citizens’ attitudes toward democracy, and their findings have been published in major political science journals. Although there is increasing interest in conducting surveys outside of industrialized nations, doing so entails considerable additional costs and challenges. Native speakers in the local language, such as Swahili, Japanese, or Uzbek, are mandatory, and careful and accurate translation of the survey is essential. Cultural differences may also create unexpected challenges for the pollster, and the usual limitations of probability sampling almost certainly are magnified in cross-national survey research. According to the 2000 U.S. Census, 97.6 percent of American households have telephones; in some other nations, however, far fewer households have them. This reality may require in-person interviews for some cross-national surveys, with the attendant expenses for travel, hiring and retaining interviewers, and other challenges.

PUBLIC OPINION AND GOVERNMENT RESPONSIVENESS

Political scientists have identified two major orientations adopted by government officials in response to public opinion: the delegate and the trustee orientations. The
“delegate” attends closely to, and follows, public opinion. Consider a lawmaker who favors stricter gun control laws, but whose district has a majority opposed to them. This lawmaker would act as a delegate by setting aside her own views and voting consistent with the majority in her district. The “trustee” often takes public opinion into account, but is more willing to vote based on personal views, or on the perception of what is best for the district. For trustees, then, lawmaking is more often independent of public opinion. In the example above, the trustee might vote in favor of tightening gun control laws, motivated by personal convictions. In general, delegates are more likely to follow public opinion, while trustees are more likely to act independently of public opinion and try to lead it, which would include educating constituents on “why I voted this way.”

Both the delegate and trustee orientations can pose problems for lawmakers. For delegates, following public opinion can be difficult if decisions need to be made on issues that pollsters have not included in their surveys. Furthermore, some thinkers, like the journalist Walter Lippman, have argued that many people lack knowledge of or interest in political issues, and thus are susceptible to manipulation by propaganda from political elites. Similarly, the political scientist John Zaller has analyzed survey responses, finding that some respondents “fabricate” survey responses on the spot when poll questions center on topics they know little about. These “nonattitudes,” Zaller contends, are a growing problem for survey researchers, given that Americans’ knowledge of and interest in politics have declined. For trustees, ignoring public opinion to cast votes based on personal convictions can have electoral consequences. An official who often votes against the views of a majority of constituents, especially on high-profile issues, risks electoral defeat.

Although the evidence does not always demonstrate a causal relationship, it is likely that public opinion influences policy more often than not. The political scientist Alan Monroe found in 1979 that when public opinion favors a policy change, that change occurs 59 percent of the time. Likewise, when opinion favors maintaining the status quo, the policy change occurs only 24 percent of the time. Similarly, the political scientists Robert Erikson, Gerald Wright, and John McIver found in 1994 that states with conservative opinions produce conservative policies, while states with liberal opinions produce liberal policies. Public opinion, then, appears to have policy consequences, and government officials do respond to public opinion more often than not. More generally, understanding public opinion is valuable in the realms of business (through market research), the media (through tracking and other media-sponsored polls), academia, and government.

PUBLIC POLICY
Public policy refers to a set of interrelated decisions governments make to select goals where the market is not working. Governmental officials establish laws and institutions to correct the perceived problems in a continual process that involves elected officials, governmental employees, lobbyists, and public-policy experts. As social scientists developed more methods and tools, both law and public-policy analysis, originally conceived of as a branch of political science, expanded to include all social scientists, but in the twenty-first century public-policy analysis is dominated by lawyers and economists.

Public policy is the making of governmental rules and regulations to benefit not one individual but society as a whole. It asks, what is the best way to conceive and evaluate policies aimed at the public as a whole and its various subgroups? Who benefits? How much does it cost? It runs through a political process, but economic, social, legal, and psychological influences help determine the possible choices and measured impacts. Often, the results of a public-policy choice are measured in statistical terms so as to seem as objective as possible.

According to Thomas A. Birkland (2005), consensus is lacking on a more precise definition of public policy. Birkland outlines several possible definitions of public policy, always starting with the actions of government and the laws and appropriations that determine those actions. Birkland then indicates that the elements common to all
definitions of public policy are: (1) It is made in the name of the “public”; (2) it is generally made or initiated by government; (3) it is interpreted and implemented by public and private players from corporations and nonprofit institutions; and (4) it also includes what the government chooses not to do.

While the study of politics has a long history, the systematic study of public policy, on the other hand, can be said to be a twentieth-century creation. It dates to the Progressive Era, when early social scientists began to recommend and rank possibilities for solving public problems. Then public policy included policies having to do with crime, poverty, health, education, and foreign affairs. Later it expanded as problems changed, and by the close of the twentieth century also included policies bearing on energy, the environment, defense, sex (e.g. same-sex marriages, sexual education and the like), and other social welfare issues. It is difficult to conceive of a united “department of public policy” because it is interdisciplinary by its very nature. It also expands beyond social science to the formation of policy objectives that are value laden. Scholars and researchers from a wide range of disciplines use different tools and methods. It takes a skilled social scientist to explain clearly a complex program such as Medicare to decision makers and other parties in the public-policy debates.

Marilyn Moon (2006), though, offers one of the best such explanations by explicitly, systematically, and logically describing and analyzing a public-policy program that offers what the market fails to do: health insurance for an aging and disabled public. Policy makers are wholly confused about how the program works and what alternatives are available to them. Moon’s book creates a primer by translating social science research into public policy. She is an applied economist who understands perhaps the most complex public-policy program in the United States, both as a matter of law and governmental practice. Her interdisciplinary analysis examines the alternatives of a national program that must work through the states and reach people on the local level. She clearly lays out criteria for evaluating the current Medicare program and how well it is working.

Since the biggest United States public programs are defense, Medicare and Medicaid, crime prevention, and education, she sets a high standard for describing and analyzing these other billion-dollar allocations. For example, nearly every nation-state has an organization to defend itself from foreign threat. But how best is this organized? Most nation-states, and even some subgroups, have an army and air force. But how should these forces be paid for (economics), organized from members of the population (sociology), positioned (geography), related to the legal system (law), dealt with in terms of individuals of the nation or subgroup (psychology), and best measured as to its effectiveness (statistics)?

Yet because the subject matter that fits into the category of social sciences evolves in parallel with societal changes, new fields of study, issues, and concepts will be added, such as the ethics of censorship, the value of income distribution, proper support of the arts, public sanction of same-sex marriage, and the psychological and economic aspects of helping people age with dignity. But all vexing policy problems require more than social sciences can deliver. They involve value judgments.

Usually the different avenues contemporary public policy takes are determined by the problems of the day. For example, as the late twentieth century spawned a whole new batch of medicines, nation-states and subgroups had to figure out how to handle health care in different ways. One can have a national system of health care delivered and paid for in any number of ways. These usually range from each person who is a member of the nation paying for his or her own care to insurance by corporations to governmental units handling the needed tasks. Most often it is some mixture of systems in flux.

How do social scientists communicate new approaches to public policy? There are the usual books and journals. But key are conferences that bring scholars of different social sciences together. A conference on aging issues might include not only social scientists but also medical researchers, operators of assisted-living facilities, and a plethora of experts to discuss ways to coordinate research efforts on policy opportunities and reform agendas.

These conferences might be funded by the National Institutes of Health and other national agencies, state agencies on crime prevention, or local schoolteachers and administrators. Public-policy agencies on a national or international level can offer and pay for conferences that no single group can afford. So, for example, all nation-states want the best tools to prevent disease. In the United States, this is done by the federal government’s National Institutes of Health, or NIH. It does some of its own research on a campus in Bethesda, Maryland (just outside Washington, D.C.), and by making grants of money to university researchers. Profit-seeking corporations usually do little of this basic research because it is not a profitable investment.

We can rank public-policy commitments by the amounts of money spent. In advanced capitalist nations, these commitments prominently include defense, social insurance, health care, and education. Defense and social insurance are usually provided collectively by the nation, while education is far more fragmented, usually at the local and state level in the United States. Health care is an issue everywhere, for it is evolving as the possibilities of cures and prevention increase.
The policy process (and the input of public-policy experts) depends on the degree of democracy of the nation-state. If some form of democracy is in play, then lawmakers at the federal, state, and local levels are voted into office and asked to make public policy that is best for their constituencies. But in more autocratic nations, the decisions are simply made at the top and implemented. At the beginning, this seems easy because basic needs for the whole are paramount. But as these policies are translated into practice, it becomes far more difficult because special interests lobby for laws and policies they claim are best for the whole but also (less articulated) best for them as a group.

In the twentieth century schools and departments of public policy in universities have developed. They usually take the form of an interdisciplinary center for social science applications to government, education, health, social welfare, and the like. Most major research universities have a school of public policy. It usually contains a core of tenured faculty, but the majority of the faculty is drawn from allied departments such as economics, sociology, psychology, and political science, as well as from medical and law schools. Many public-policy analysts earn a Master of Public Policy (or a Master of Public Administration) in such programs, while others earn specialized degrees, such as an MEd for specializing in educational policy or an MSW for specializing in social welfare policy.

Trained graduates can go to work for governments, lobby organizations (such as AARP’s Public Policy Institute, headquartered in the nation’s capital), advocacy groups (such as the Medicare Rights Center in New York City), or think tanks such as the Brookings Institution and the RAND Corporation. Later, usually with experience, they can return to teach at universities such as Harvard, Michigan, Wisconsin, and the University of California at Berkeley, to name but four of the more notable and sizable public-policy programs.

PUBLIC RIGHTS

Within the domain of thinking about rights, the preponderant nineteenth-century typologies distinguished between natural, political, civil, and social rights, with varying accounts of the relationship among them. In the 1860s, however, as political activists and legal thinkers grappled with the question of the scope and meaning of freedom for those who had previously been held as slaves, the concept of public rights was introduced into debate as a means of articulating resistance to inequalities associated with castelike systems of privilege.

Capturing the element of dignity and honor at stake in the treatment of citizens in public places, public rights encompassed what is now termed equal access to public accommodations and public transportation, and could be extended to prohibit segregation in public schools. The concept and content of public rights, however, were strongly opposed by conservatives, who associated its claims with what they called “social equality”—a derogatory term they used to evoke images of forced physical intimacy across racial lines, particularly the proximity of black men to white women. Although the term public rights was lost to jurisprudence in the United States by the late 1870s, much of its content would subsequently be incorporated into the expanded notion of civil rights that underlay the twentieth-century movement for justice for African Americans.

The formal category of public rights seems first to have been proposed in the 1830s by an Italian jurist, Pellegrino Rossi, who held the chair of Constitutional Law at the Collège de France in Paris. True to the constitutional monarchy under which he had been appointed, Rossi believed that the state could limit political rights, arguing that access to suffrage should depend on capacity, which he assumed to vary among different groups of citizens. In keeping with the anti-aristocratic spirit of the earlier French Declaration of the Rights of Man and of the Citizen, however, Rossi endorsed universal public rights, within which he included rights of assembly, conscience, and free expression. These, he argued, were fundamental rights of humans as social beings and should not be restricted on the basis of privileges of birth or presumed capacity.
The phrase public rights was introduced and given an expanded meaning in the United States as the end of slavery and the debates over the Fourteenth Amendment to the Constitution made it clear that men and women who had been considered property would now become the bearers of rights. Everything turned on the question: Which rights? Moderates contended that former slaves and other persons of African descent might henceforth hold certain civil and political rights, but that social rights fell outside the proper scope of legislation. This formula could leave broad areas of public life—including education, public transport, and public accommodation—outside the action of equal-rights lawmaking.

In 1867 and 1868, a group of radical delegates to Louisiana’s Constitutional Convention proposed an alternate schema: The state should guarantee to all its citizens “the same civil, political, and public rights and privileges.” This construct, advanced by members of an alliance of long-free men of color, local and northern-born white radicals, and former slaves, allowed the delegates to avoid the word social, which their enemies had used to accuse them of seeking an unearned “social equality.” The radicals won, and the 1868 Louisiana Constitution mandated equal access, independent of color, to public transportation, public accommodations, and places of public entertainment, including saloons and restaurants. For a decade, this document provided a framework for racially integrated schools and permitted victims of discrimination in the public sphere to sue for damages.

A commitment to equal public rights for all citizens subsequently appeared in the platform of the national Republican Party in 1872 and again in 1876. With the reversal of Reconstruction in the late 1870s, however, the concept almost vanished. Newly ascendant white-supremacist Democrats expunged it from the 1879 state constitution in Louisiana, and national Republicans dropped it from their platform.

Among some equal-rights activists, however, a variant of the concept remained alive and well. As southern Democrats pushed forward with the political project of white supremacy in the 1880s and 1890s, restricting suffrage and imposing state-mandated segregation, the lost language of the 1868 Louisiana Constitution became a touchstone for such figures as Rodolphe Desdunes, a cigar seller who helped mount the challenge to segregation on the railroads that led to the U.S. Supreme Court case Plessy v. Ferguson. The Citizens’ Committee that arranged Homer Plessy’s test case drew on a broad base of urban and rural activists, including artisans, schoolteachers, and even some Cuban émigré cigar workers, one of whose leaders framed his support explicitly in the language of “public rights” (Scott 2005, pp. 88–93, 151).

When the case reached the Supreme Court, Plessy’s attorneys invoked broad anticaste principles rooted in an expansive concept of national citizenship. Their arguments went down to defeat before the Court, whose majority accepted the white supremacists’ sleight-of-hand that portrayed Plessy’s opposition to caste distinctions as a presumption to “social equality” that no law could impose. The language of the briefs drafted for Plessy was nonetheless echoed in Justice John Marshall Harlan’s memorable dissent, in which he held “caste” to be antithetical to the principles of the nation.

In its time, the concept of equal public rights provided a coherent basis for claiming formal respect in the public sphere. Its use rested on a coalition and a movement that did not prevail, but it left a conceptual legacy for those who would subsequently renew the struggle under the name of civil rights.

PUBLIC SECTOR

The term public refers either to the people affected by some property or activity or to government property and activities. The public sector is the governmental sphere of an economy. Economists classify four basic functions of the public sector: the provision of collective goods and services, the redistribution of income and wealth, the promotion of stabilization and growth, and the prevention of social costs and market failures from crime, pollution, congestion, and monopoly.

The word public refers to the public sector in the following terms: public administration, public debt, public economics, public employment, public finance (and rev-
Public Sector

The branch of economics that studies collective decisions and decisions that affect the public is called public choice. The field includes voting, bureaucracy, and the policies enacted by elected officials. Public finance, a much older branch of economics, examines actual and optimal taxes and incentives as well as the economic impact of fiscal policy. A key concept in public choice is rent seeking, the influence of various interests that seek to transfer wealth (unearned rents) to themselves at the expense of the public. But also the median voter theorem states that policy makers cater to the voters in the middle of a policy spectrum. Thus the policy outcome can vary. Public choice as a field of study does not imply any particular policy outcome or normative viewpoint.

THE GROWTH OF THE PUBLIC SECTOR

In ancient Greece public referred to politics and government, the private sphere being the family and nongovernmental enterprises, such as farming and trade. Until the 1800s public sectors were mainly concerned with the military, taxation, legislation, relief for the indigent, administration of state land, maintenance of royalty, public works, and control of trade. During the 1800s the public sector expanded into municipal police and governmental schooling. In the latter 1800s, responding to socialist movements, Germany, followed by Great Britain and other countries, expanded the public sector to include social security and other welfare programs on a national scale. In the early 1900s central banking extended government further into money and banking, especially after countries switched from commodity money to fiat money. Russia in 1917 established the Union of Soviet Socialist Republics, which put its whole economy in the public sector.

The income tax as well as the value-added taxes established in Europe and other countries facilitated a great expansion of the public sector. In the United States there was a large expansion of government under the New Deal of President Franklin Roosevelt, including the establishment of Social Security. The public sector expanded again during the 1960s with the introduction of Medicare and Medicaid. In the late twentieth century the public sector became more involved in protecting the natural environment.

Wagner’s Law, named after Adolph Wagner, states that economic growth is accompanied by an increased gross domestic product (GDP) share of the public sector. The public may demand greater collective services, such as better education, as wealth increases, but some theorists propose that much of the expansion is in response to previous interventions that create distortions. For example, a city policy that limits development can result in higher rentals, which then induce the city to respond with rent control. Governments have also increased their role in economic development by providing education, research, and infrastructure. Many government programs, such as medical care and housing subsidies, are in response to poverty and economic insecurity. War has also ratcheted up the public sector, as the size of government rises during wartime but then does not return to its prewar level. Governments now commonly seek to promote economic growth with investments in infrastructure and by the expansion of money and credit. Governments also finance activities such as basic research when markets are perceived as failing to provide sufficient amounts, as the benefits apply to the economy as a whole.

PUBLIC SECTOR PROVISION

The government can directly produce goods and services such as the military, postal service, schools, streets, highways, parks, police, and fire protection or contract out the production to private enterprise. Much of governmental expenditure consists of transfer payments. By imposing costs, government regulations can have the effect of taxation. For example, if firms are required to provide medical insurance to employees, that has a similar effect to taxing the firms and using the funds to subsidize the insurance.

Taxation has a social cost beyond the funds paid to government, an “excess burden” or “deadweight loss” caused by the reduction of output and investment caused by taxes. The amount of deadweight loss depends on the amount of the tax and the elasticity of the item taxed, that is, how its quantity responds to a change in price. Since land has a fixed supply, taxes on land value have no deadweight loss. There is also no excess burden if the tax, such as a pollution levy, also reduces social costs by a greater amount. User fees, based on benefits, also have no excess burden.

The effects of government borrowing depend on how the funds are borrowed, how the funds are spent, whether the spending stimulates the use of untapped resources, and the extent to which various financial investments substitute for one another. In some cases, government borrowing can raise interest rates and crowd out private investing, but in other cases, especially if there is high
unemployment, if funds are borrowed from abroad, if the borrowing is for productive investments complementary to private investment, if private savings rise to offset government borrowing, or as noted by Benjamin M. Friedman (1978), if the borrowing uses short-term bonds that substitute for money, government borrowing can result in “crowding in” or a stimulus to private investment. Many economists think that optimally government should borrow money only for productive investments, including enhancements to human capital, and use current revenues for its collective consumption, such as military operations.

The size of the public sector can be measured by the total amount of spending, the share of GDP, workers employed, and public sector assets and liabilities. The U.S. federal government spent $2.5 trillion in 2005, 20 percent of GDP. State and local governments spent from their own sources $1.4 trillion, 11 percent of GDP. The relative size of government for the members of the Organization for Economic Cooperation and Development with developed economies grew from 27 percent in 1960 to 48 percent in 1996. Government outlays as a percentage of GDP in 1996 were 44 percent in the United Kingdom, and Denmark was the highest at 61 percent.

MACROECONOMIC ACTIVITY AND INTERNATIONAL TRADE
A large public sector can increase the trade deficit to the extent that taxation makes exports more expensive and to the extent that government spends its funds abroad, as in the case of a war. Governments mostly affect international trade with tariffs and restrictions, such as quotas, and with policies that affect foreign-currency exchange rates.

LABOR AND THE ENVIRONMENT
In most developed economies, public sector labor is about 15 percent of employment. Several studies have concluded that workers in the public sector tend to be better paid than those in the private sector. Government workers typically are under a civil service system by which it is difficult to fire an unproductive worker. A more fundamental element of the cost of labor in the public sector is Baumol’s cost disease, put forth by William J. Baumol and William G. Bowen (1966), who argued that productivity in services such as an orchestra or education has changed little compared to that in manufacturing, which explains the increase in relative costs in the service-intensive public sector.

With global warming recognized as an urgent issue, people increasingly seek remedies in government policy. The taxation of pollution is more efficient than regulations, as the former permits firms and households to adjust according to their individual costs and benefits. Pollution permits that trade in a market are also used to increase the cost to business of polluting more. Environmentalists have proposed a “green tax shift” that increases pollution charges while reducing taxes that have an excess burden, a policy that would minimize the economic costs of reducing pollution.

Advancing technology has meanwhile reduced the rationale for some large-scale government involvement, as knowledge becomes more easily accessible and the private sector becomes more capable of providing infrastructure, such as tolled highways and decentralized utilities. Nevertheless, conflict tends to expand the public sector, so the future role of the public sector depends on the interplay of advancing technology, threats to security and the environment, and the influence of theoretical knowledge and real-world experience in shaping public opinion.

PUBLIC SPHERE
Discourse on the public sphere derives from the work of the German social theorist Jürgen Habermas, particularly with his first major work, The Structural Transformation of the Public Sphere, which first appeared in Germany in 1962, and in what some consider to be his magnum opus, The Theory of Communicative Action (1981). In these and other works, Habermas has been concerned with explicating the historical and social structural factors that have
served to inhibit or advance democracy. Given the centrality of free and open dialogue for the functioning of democracy, of particular concern to Habermas is identifying where such discussions take place and under what conditions. His guiding question has been: Where is the space in which democracy is nurtured? Habermas refers to this space as the public sphere, a term related to civil society, which refers to a realm of social life distinct from both the state and the market, where participation in public life occurs with a spirit of cooperation and a norm of reciprocity. Seen in this light, Habermas construes the public sphere as a space within civil society. By claiming that a prerequisite of a democratic polity is an autonomous public sphere, Habermas can be seen as building on the work of Max Weber (1864–1920) and Seymour Martin Lipset (1922–2006) in attempting to identify the most important social structural conditions underpinning democratic societies.

What Habermas refers to as the “bourgeois public sphere” came into its own in the nineteenth century, most fully in Britain, as a result of the triumph of capitalism and the establishment of a laissez-faire state. In contrast to the feudal era, in which the economy and polity were intimately linked, in the earliest phase of the capitalist industrial era this linkage was uncoupled. The public sphere can be visualized as being carved out between the economy and the state, being separate and distinct from them. It is an arena that is accessible to all citizens on the basis of equality and thus is not dominated or controlled by powerful economic actors or by state officials. His perspective on this sphere has been depicted as a theater where political discourse occurs.

The public sphere requires the existence of independent voluntary associations of citizens and an institutionalized apparatus that permits the unrestricted dissemination of information and ideas. Thus the panoply of organizations—ranging from local parent-teacher associations and neighborhood clubs to labor unions, human rights organizations, environmental organizations, and so on—is part and parcel of this arena. In addition, so are media committed to ensuring that citizens are informed about the vital issues of the day and to providing outlets for articulating an array of stances on issues and forums for debate and dissent.

Critics of Habermas contend that he tends to romanticize the public sphere during its earlier years, confusing his ideal vision about how it should have functioned with the reality of the historical situation, which involved from its inception persistent intrusions of powerful economic interests and the repressive tactics of the state. The result was that the public sphere never managed to be as autonomous as he seems to think. This may be a somewhat unfair characterization of Habermas’s position because he provides ample evidence of being aware of the limitations of actual existing public spheres in the past. He does think, however, that public spheres in the past exhibited greater autonomy than their contemporary versions.

At the same time Habermas leaves himself open to charges of utopian thinking, especially when he develops the ideal of a state of undistorted communication, free from coercion and restraint. In his view, democratic decisions arise dialogically. In an ideal speech situation, people talk to others to come to an understanding of which ideas and values are best, not to manipulate others to get one’s way. In other words, he assumes a willingness on the part of citizens to freely embrace the better argument. There are examples of situations in which this ideal seems to have been more or less realized, such as old New England town meetings and Quaker meetings. The participants in these examples can be fairly depicted as being cooperative, tolerant, critical, self-reflective, and rational, whereas the differences among them in terms of both economic status and levels of human capital are not great.

Two other criticisms have been leveled at Habermas’s portrait of the public sphere. First, some feminists contend that he is insufficiently attentive to the relationship between the private and public spheres and its implication for gender relations. Second, he has been accused of operating with an overly rationalistic and overly civilized view of human nature.

Habermas has expressed concern that the public sphere in what he describes as “late capitalism” is threatened by what he calls “refeudalization.” What he refers to is the tendency to link or integrate the economy and the polity in a way quite at odds with their separation in the earlier period of capitalist development. Given his focus on communication, it is not surprising that he is particularly apprehensive about the concentration of media power in the hands of political and economic elites. Large media conglomerates have arisen to choke dissent voices out of the market, and these corporations, far from being independent of political power, serve as apologists for it. The result is that genuine public debate has given way to propaganda and increasingly sophisticated public relations.

Although the portrait he paints might lead to despair regarding the future of democracy, Habermas presents a cautious optimism. In particular he sees in the new social movements—environmental, antinuclear, peace, feminist, and so forth—potential for change. These movements have abandoned any belief in the possibility of revolutionary change, opting instead for radical reforms and a commitment to nonviolent change. Underlying his tempered hope for the future is a particular understanding of human nature. It presupposes that people are by nature political and thus concerned about and willing to participate in issues related to the well-being of society as a whole.
Public Utilities

Public utilities are firms that are sometimes synonymous with natural monopolies. Some examples of public utilities include the Tennessee Valley Authority and Illinois Power.

These organizations are generally so called because there is structurally no room for market competition—one firm can “naturally” produce at lower costs than competitors who are eventually priced out of the market. Thus, natural monopolies tend to be regulated by governments in the public interest. However, being a natural monopoly is not a necessary prerequisite for government regulation. Industries that are not natural monopolies may be regulated for a number of reasons, including service reliability, universal access, and national security.

Public utilities generally supply goods or services that are essential, like water, electricity, telephone, and natural gas. For example, the transmission lines for the transportation of electricity or natural gas pipelines have natural monopoly characteristics in that once these lines are laid by one utility, duplication of such effort by other firms is wasteful. In other words, these industries are characterized by economies of scale in production.

Left to themselves, private utility companies would make decisions that are most profitable for them. Such decisions generally involve too high prices and relatively little service compared to competitive conditions. These decisions may or may not be in the best interests of the society. The government or the society would like to see these services being economically accessible to all or most of the population.

Not all utility companies are in the private sector. In many countries, utilities are owned by the government. Generally, in these cases, the government creates autonomous bodies for government utilities to prevent them from day-to-day political interference. In such instances, the government utilities’ goals are better aligned with societal goals; however, they tend to be less efficient than their private sector counterparts.

Two main issues facing public utilities are coverage of service area and pricing. Alternately stated, the regulators try to balance the competing aims of economic efficiency and social equity. Economic efficiency generally requires that markets be left to work by themselves with little intervention. Such instances are usually not equitable or fair (some consumers might be priced out of the market). Equity issues demand that everyone gets the service at a “just” price. However, these instances can turn out to be inefficient (think about the cost to an electric utility of having to run cables a number of miles especially to serve one or two remote fishing cabins that are used sparingly).

In general, the pricing of the services of public utilities is problematic. As mentioned above most public utilities are structural monopolies, implying that there is no room for competition in the market for services they provide. However, if they are left alone to price like monopolies, the resulting price is too high and a large part of the market area may not be served. While the utility companies have no complaints about such arrangements, given the essential nature of the services they provide, the society would like to provide such services to all or most of the population. Think, for instance, about the undesirability of denying heat to someone in the winter. Hence, their pricing actions are regulated.

However, these decisions are somewhat problematic. If these utilities are mandated to set prices at the low competitive levels, they generally end up making losses. So there continues to be an ongoing tussle between regulators and the utility companies regarding a “fair” price between the monopoly and competitive levels.

Common alternate pricing actions include (1) setting prices equal to average production costs and serving the maximum area possible; (2) rate of return regulation; and (3) price cap regulation. Under average cost pricing, the utility is assured of breaking even, since the prices equal average costs. The equity aspects are somewhat met since most of the market is being served. However, the regulated firm lacks incentives to minimize costs. Under rate of return regulation, the regulators let the firms charge any

Peter Kivisto
price, provided the rate of return on invested capital does not exceed a specified rate. Whereas such regulation is flexible in allowing pricing freedom and frees the regulators from monitoring prices, a key drawback is that such regulation can lead to overcapitalization. In other words, when the rate of return is fixed at 5 percent, then the firm can charge higher prices by investing more in capital than it would otherwise (i.e., 5% of $10 million is greater than 5% of $6 million). Price cap regulation directly sets a limit on the maximum price charged by regulated firms. This type of regulation can result in a loss of service area. A (somewhat debated) plus point of price cap regulation is that such regulation induces firms to seek cost-reducing technologies because they offer a way to increase utility profits.

With technological changes over time, the nature of regulation changes in that some functions of the utility companies are “unbundled” and thrown open to free competition. New technologies might make it possible to break up the different stages of the electric generation process or natural gas transmission such that competition might be allowed to function in some stages. For example, in twenty-first-century United States and elsewhere the electricity generation market is relatively competitive and consumers are able to purchase electricity from competing vendors (generators). However, the transportation of electricity still remains a natural monopoly and continues to be regulated. Further, oftentimes the deregulation of some or all functions of public utilities might occur over time due to political-economic compulsions.

In practice, however, both deregulation and increased regulation are plagued by uncertainties, both for regulators and the firms they oversee. For instance, the firms do not know when and whether they will face additional regulation (or deregulation). The regulators, on the other hand, are unaware whether new technologies would mandate additional regulation. Another related issue facing nations involves how to make the regulations somewhat consistent across international borders so that utilities from one nation do not have undue advantages over utilities from other nations (U.S. and Canadian utilities have faced such issues following the North American Free Trade Agreement [NAFTA]).

There is some criticism of public utility regulation in that over time the regulated utilities tend to take over the regulatory agencies that oversee them (called the capture theory of regulation). Thus the societal interests that the regulatory agencies are supposed to further are somewhat compromised. The evidence regarding the capture of regulatory agencies is mixed, however. Further, some researchers, including John Galbraith in his 1973 work, have questioned the supposed underproduction by monopolies.

To summarize, whereas over time changes in environment and technology warrant changes in regulation of public utilities, the nature of markets that utilities serve generally warrants they be overseen in some form or another by government bodies.

PUBLIC WELFARE

Welfare programs represent an effort on behalf of nation-states and international organizations to provide assistance to people who are otherwise unable to take advantage of market (primarily capitalist) relations. Welfare programs emerged as a public (meaning government-funded) phenomenon following historical periods of industrialization in Western nation-states during the eighteenth and nineteenth centuries and in Asian, Latin American, and African states in the twentieth century, following the decline of colonialism.

Prior to industrialization, explanations for poverty and other forms of political marginalization abounded, most of which emphasized the failings of poor individuals themselves rather than market-based, state-centered, or international explanations. Preindustrial explanations for the existence of the poor fall into two categories. The first category follows the logic of retribution. Poor individuals have committed sins or other values-based transgressions for which the penalty was poverty. In response to such explanations, programs developed first by private individuals and religious organizations were geared toward treating the poor as criminals in fact if not by law.

The second set, paternalistic explanations, evolved from two primary origins: (1) a response to the recognition of the harsh conditions industrialization brought to urban centers, which were increasingly teeming with rural poor who had migrated in search of work; and (2) a justification for the economic exploitation of indigenous populations in colonial contexts around the world. In response to the first origin, labor laws emerged in Great Britain, France, and later the United States first to protect children, who were the first to be seen as “innocent” victims of market fluctuations. Later, through the social movements of labor unions and the rise of Marxist ideol-
ogy as a challenge to capitalism, women and, last, adult males found increased economic protection through widows’ pensions, unemployment insurance, and better protected labor negotiations.

In response to the second origin, the logic of paternalism dictated an attention to the supposed “natural and primitive” state of the indigenous poor, who then must be “developed” or otherwise socialized into market-based civilization. A different set of programs arose that focused on the mollification of indigenous resistance to the economic exploitation of colonialism and, later in the postcolonial context, the enforced economic independence of new states with limited reparations from colonial conquerors who had benefited economically from previous arrangements. In response to the needs of newly independent states, an international development movement emerged to plug some of the holes required for economic integration into world markets and increased political stability. Many international development programs were premised on this prior paternalistic logic.

Both explanations of poverty remained salient during the rise of progressive movements in industrialized liberal democracies such as Great Britain and the United States. However, a third explanation emerged following the Industrial Revolution as part of reformist, progressive activism that emphasized the role of economic institutions that were either dependent upon or responsible for the creation of vast swaths of poverty. In Western nations, the emergence of socialism as an alternative to liberalism produced hybrid political-economic models such as social democracy, which emphasizes a balance between free markets and economic equality. Northern nations such as Sweden have emerged as the archetypical models of social democracy, where public welfare includes guarantees of financial assistance, generous child care and family leave policies, housing assistance, employment protections, and disability and old age insurance. More recent scholarship has emphasized four ideal types for public-welfare provision comparisons: social democratic, liberal democratic, conservative, and post-Communist regimes.

While social democracies are attractive in terms of the safety net for the economically disadvantaged, individual citizens carry a much heavier tax burden to cover such programs than they do in liberal democracies such as the United States, where programs are not nearly as comprehensive—financially or programmatically. This fact may help to explain why there is not a direct linear relationship between the level of public-welfare provision and general citizen support for such provision. The relationship is instead curvilinear, suggesting that citizens in high-spending, social democratic Scandinavian countries level off in support, while citizens in lower-spending liberal southern European nations continue to support such public-welfare expenditures. This trade-off is one that continues to be contested within each country, with welfare program popularity also based significantly on perceptions of program recipients.

Both liberal democracies and social democracies among Western nations, however, share a comparative advantage in terms of long-term political stability, gross domestic product, and other economic resources that enable nation-states to remain relatively independent of international organizations in terms of social safety-net provision. Newer democracies—many of which emerged in a postcolonial context of limited political stability, low gross domestic product, and low availability of cash-producing resources—face ongoing struggles to provide a social safety net of cash assistance, agricultural subsidies, child care and family leave policies, housing assistance, employment protection, or disability and old age insurance. In these contexts, international organizations, such as the World Health Organization, UNICEF, the International Monetary Fund, and the World Bank, have significant influence upon nation-states’ ability to provide public welfare for their citizens.

For example, structural adjustment programs prescribed for what are called “developing” nations often require fiscal policies that substantially limit domestic public-welfare capabilities. For example, liberalizing a national economy often includes allowing significant amounts of foreign investment to enhance the economy. However, with such investments comes the provision of corporate incentives that can limit labor protections for workers—including less onerous minimum wage laws, worker safety regulations, and labor union protections. The trade-offs between public-welfare programs and economic stability for new nation-states is an ongoing challenge. However, a new framework promises to question some of these trade-offs and the paternalistic premises that undergird international development programs. The “empowerment” literature changes the social construction of public-welfare recipients—from either domestic or international programs—into one that focuses on the existing capabilities of the poor and more democratically includes them in program design and funding decisions. Still new, empowerment logic is widespread in the area of microlending, which encourages market integration one small business owner at a time.

In “developed” nations public-welfare programs are more commonly defined as protections against the vagaries of the market—cash assistance for those who do not work, whether because of unemployment, disability, or old age. The security of these programs is based on more domestic considerations than those of developing nations. In countries such as the United States, Great Britain, and France, public policy debates surrounding the shrinking of public-welfare programs boils down to
debates that focus again on the people who might benefit—whether they are deserving of assistance or not. As one might expect, those who are deemed deserving of assistance—those, for example, who have “paid into a system” through decades of taxes on their wages—are less likely to have benefits cut than those who are presumed to receive “something for nothing.” To the degree recipients are perceived as deserving, programs are more popular. When recipients are perceived as undeserving, programs are less popular. Such explanations continue to shed light upon the size and limits of welfare state disbursements to the poor and to debates surrounding the boundary lines between the “deserving poor” and the “undeserving poor.”

PULLMAN PORTERS

Ironically, the position of Pullman porter, which was designed to capitalize on the legacy of slavery, instead became the catalyst for both the formation of an African American middle class and the first major African American labor union (the Brotherhood of Sleeping Car Porters). In addition it was linked to the emergence of the U.S. civil rights movement in the twentieth century.

At the end of the Civil War, the Pullman Sleeping Car transformed travel in the United States. Though sleeping cars on trains had been used before, the Pullman was the first comfortable, indeed luxurious, sleeping car, and it ushered in a new era of comfortable cross-country train travel. The job of the Pullman porter included loading and unloading passengers and their luggage, keeping toilet and general-use areas and cabins clean, and turning down and putting up the folding upper and lower beds. The porter also took care of patrons’ personal needs, such as boxing ladies’ hats, sending letters and telegrams, setting up card tables, stocking coolers with ice, serving food and drinks in the dining car, and selling cigarettes, candy, and playing cards. When necessary he also took on the chores of the conductor, though he was never paid a conductor’s wages. For many years porters were on call twenty-four hours. As envisioned by founder George Pullman (1831–1897), the porter’s role was to supply the average traveler with the luxury of a servant for the duration of the trip. Pullman specifically modeled the Pullman porter after the plantation house servant, and he intended the jobs to be filled by the recently freed slaves.

The Pullman Company, headquartered just outside Chicago, quickly became the largest single employer of African Americans, and Pullman porter positions were among the most prestigious jobs available to them. However, the wages and working conditions were poor compared to those of white Americans. Porters represented the first foray for African Americans into the middle class, but this was due more to the perceived prestige of the position and the experience of being well traveled than to the economic gains. That said, many of the Pullman porters were highly educated. Nonetheless, this was the best employment they could obtain in Jim Crow–era America, and the company kept porter hours long and wages low, forcing them to rely upon tips as a significant part of their income. Until the formation of the Brotherhood of Sleeping Car Porters (BSCP) in 1925, porters were never paid more than office boys, the lowest ranking white employees.

In a degrading act of racism, whites routinely called all porters “George” after George Pullman, following an older racist custom of naming slaves after their masters. The Society for the Prevention of Calling Sleeping Car Porters “George” (SPCSCPG) was formed in 1916 to pro-
mote the elimination of the practice. The SPCSCPG lasted until 1941 and at its peak counted more than 31,000 members, including George Herman “Babe” Ruth and King George V. Although the SPCSCPG ostensibly was formed to eliminate a racist practice stemming from the slavery era, some scholars speculate that the society was formed as a way for white railway workers and frequent Pullman passengers to distance themselves from the African American porters.

In 1925 the Pullman porters formed the BSCP and chose A. Philip Randolph (1889–1979), the well-educated editor of Harlem’s Messenger Magazine, as president. Randolph had never been employed as a porter and therefore could not be disciplined by the Pullman Company. Hence Randolph maintained complete control of the direction of BSCP throughout his long tenure as the organization’s president and relied on his regional delegates, most notably Milton P. Webster of the Chicago chapter, to maintain the day-to-day activities of the union.

The most important issues for Randolph and the BSCP in the early years were to win recognition of the BSCP as the sole authorized representatives of the Pullman porters and then to deal with the industry’s split labor market that placed African Americans in lower-paying positions or paid them less even when they were doing the same work as whites, such as conductor duties. After a long and contentious fight, the first goal was accomplished, and progress was made toward achieving the second goal.

The Pullman Company and other employers of the period were not alone in their determination to protect the split labor market. Labor unions were unwilling to embrace African Americans, typically seeing them as competitors rather than allies. However, by 1929 the BSCP was admitted into the American Federation of Labor (AFL). Randolph used his position in the AFL to push for greater acceptance of minority workers by stressing the common economic goals of workers rather than racial differences, and he was instrumental in gaining wider acceptance of African Americans in many industries.

In 1941 Randolph and other BSCP organizers called for African Americans to march on Washington, D.C., to protest racial discrimination in the defense industries. Randolph decided that the march had to be an African Americans–only protest, not to distance African Americans from supportive whites but to establish African American control over their own destinies. Once it became obvious to President Franklin D. Roosevelt that Randolph had succeeded in effectively organizing a massive protest, he signed Executive Order 8802, the Fair Employment Act (1941), which prohibited defense and other government-related industries from discriminating against African Americans. Although this order carried no punitive measures for those who did not comply, it officially acknowledged the need for the government to address racial issues. Randolph called off the march on Washington, but the group continued to work on civil rights issues.

In 1982 Jack Santino produced and directed Miles of Smiles, Years of Struggle: The Untold Story of the Black Pullman Porter, a documentary chronicling the organization of the BSCP and the impact this group had on the U.S. civil rights movement. In 1983 Santino followed up with a striking article in the Journal of American Folklore that documented through oral history the racial stereotypes, racial violence, and other forms of racial discrimination faced by African American porters, who were by then in their eighties and nineties. Interestingly many of the instances of racism and abuse discussed by the former porters occurred long after the formation of the BSCP.

PUNCTUATED EQUILIBRIUM

Punctuated equilibrium is a descriptive hypothesis in evolutionary biology concerned with macroevolutionary dynamics specifically at the level of speciation. Punctuated equilibrium holds that most species originate by the splitting of a population during brief geological periods (punctuations), and that subsequently species persist with only
Punctuated Equilibrium

relatively moderate morphological change (stasis) for the remainder of their existences. “Evolution by jerks,” as punctuated equilibrium has been lucidly labeled, is usually contrasted with phyletic gradualism (“evolution by creeps”), which states that species evolve uniformly and slowly by the gradual transformation of large populations. Proposed jointly by paleontologists Niles Eldredge and Stephen Jay Gould (1941–2002) in 1972, punctuated equilibrium immediately lit a scientific controversy that has smoldered ever since.

Punctuated equilibrium was, however, hardly controversial at its inception. As a general characterization of macroevolutionary processes, it was largely presaged by Hugh Falconer (1808–1865) and Charles Darwin (1809–1882) in the mid-nineteenth century and later echoed by Hermann J. Muller (1890–1967) and George Gaylord Simpson (1902–1984) in the early twentieth century. Eldredge and Gould postulated their version of the hypothesis as a logical extension (into paleontology) of Ernst Mayr’s (1904–2005) ecological theory of allopatric speciation (1963), which was widely considered the dominant theory of speciation. Allopatric theory proposes that speciation occurs when a smaller subpopulation becomes geographically isolated from its parent population. Over time, this peripheral daughter population diverges in isolation until it can no longer interbreed with the parent. Speciation as such happens relatively quickly in a small population and in a limited geographic range. Due to the relative brevity of this localized speciation event, intermediate morphologies will be unlikely to fossilize and will be rare even if they do, producing an apparent paleontological pattern of stasis punctuated by discontinuous speciation events.

While born of an orthodox evolutionary theory, punctuated equilibrium has been associated throughout its existence with more radical evolutionary concepts. The scientific controversy over punctuated equilibrium is multifaceted, but it has largely coalesced around three related issues: (1) whether punctuated equilibrium is “Darwinian”; (2) whether stasis truly is the predominant mode of evolution in the fossil record; and (3) whether the proposed mechanisms for both stasis and punctuations are valid.

One of the easiest means to draw attention to an evolutionary concept is to pronounce it “anti-Darwinian,” and punctuated equilibrium has been no exception. Both proponents and detractors of punctuated equilibrium often claim that Darwin explained the incompleteness of the paleontological record as solely the result of the imperfect geological preservation of fossils. However, as pointed out by Frank H. T. Rhodes (1983, 1987), Darwin in fact devoted the larger part of chapter 10 of On the Origin of Species (titled “On the Imperfection of the Geological Record”) to explaining how “gaps” in the fossil record are a direct consequence of speciation processes and the nature of natural selection. Like Eldredge and Gould, Darwin thought it likely that most species exist in a state of morphological stasis, only intermittently broken by bursts of localized change and speciation. Darwin found this point so important for understanding the paleontological record that he reiterated the argument in three separate chapters (Darwin [1872] 1993, chap. 4, “Natural Selection,” p. 152; chap. 10, p. 428; and chap. 15, “Recapitulation and Conclusion,” p. 619).

Furthermore, in debates over punctuated equilibrium, the term gradualism has been used in at least two different senses. Eldredge and Gould’s phyletic gradualism concerns the tempo of evolution, entailing evolutionary trajectories that are geologically slow, constant, and unidirectional—a concept pointedly contrasted with the rapid speciation described by punctuated equilibrium. For Darwin, however, gradual has little to do with rate ([1872] 1993, pp. 312–317). Rather, it means that evolution by natural selection advances in small “grades” that are dependent on a population’s normal genetic variation. Morphological change therefore can be genetically gradual and geologically rapid. While phyletic gradualism may have been a widespread evolutionary assumption in the twentieth century, it cannot be pinned on Darwin himself. Thus, given the significant overlap between the tenets of punctuationism and Darwin’s views, punctuated equilibrium is resolutely “Darwinian.”

Whether the fossil record truly displays a predominant pattern of stasis continues to be an active area of paleontological research. Punctuated equilibrium is most readily tested when geological strata are well resolved temporally with abundant fossil preservation. Empirical studies have resulted in mixed appraisals, with a roughly equal spread among those supporting phyletic gradualism, punctuated equilibrium, or a third “hybrid” process that may be described as punctuated gradualism (Erwin and Anstey 1995). Probably the most tangible contribution of the punctuated equilibrium controversy has been the widespread acceptance of Gould and Eldredge’s claim that “stasis is data.” Lack of morphological change is an evolutionary pattern that warrants an explanation.

The assortment of mechanisms that Gould and Eldredge have proposed to explain stasis and rapid speciation is the most contentious aspect of the punctuated equilibrium debate (Coyne and Charlesworth 1997). Eldredge and Gould initially implied that punctuated equilibrium is explained adequately by Mayr’s mainstream theory of allopatric speciation. However, they successively suggested numerous additional “non-Darwinian” mechanisms, including saltational mutations and species selection (Gould 1980, 2002), none of which have been broadly accepted. Emphasizing an antireductionist plural-
ism, Eldredge and Gould further claimed that each of these speculative mechanisms was significant for its potential to decouple lower-level genetic processes from upper-level macroevolutionary trends. Perhaps ironically, the punctuationist paradigm has been adopted more recently by molecular biologists, who have found within in vitro evolution experiments analogous patterns of stasis inter-leaved with rapid genetic change (Elena et al. 1996). Thus, punctuated equilibrium may ultimately find its raison d’être in the very reductionist realm so vigorously opposed by Gould: molecular evolution via the “selfish gene.”

PUNISHMENT
The concept of punishment originates at least as far back in philosophy as Socrates (Cooper and Hutchinson 1997), and the practice of punishment as a social institu-

There are at least three important philosophical and ethical questions concerning punishment. The first concerns its nature. Much confusion can result if the nature of punishment is not understood to amount to some kind of harsh treatment of the offender or the harmful wrongdoer. Although punishment is legitimate, institutionally implemented harsh treatment for the commission of a legal offense (Hart 1968; Feinberg 1970; Rawls 2000; Corlett 2006), it might well have side effects—even positive ones—such as moral education or rehabilitation. By “harsh treatment” is meant some form of corporal punishment, incarceration, fines, or the like. But it is important not to confuse punishment with deterrence, moral education, or rehabilitation. These are not forms of punishment, because punishment is not properly defined necessarily in terms of deterring, morally educating, or rehabilitating offenders. To think otherwise is to beg the question in favor of one of the theories of punishment considered below. This is not to say, however, that genuine punishment cannot deter future harmful wrongdoings, morally educate, or rehabilitate in some ways on some occasions.

A second question concerning punishment amounts to a set of questions raised by Anthony Quinton (1954), John Rawls (1955), and Stanley Benn (1958). The first pertains to the moral justification of the institution of punishment itself, while the second regards the moral justification of particular forms of punishment. Clearly, the belief that punishment is morally justified does not mean that all forms of punishment are justified, though it would seem that for any particular form of punishment to be justified, the institution of punishment itself must be justified. Attempts have been made to reconcile major theories of punishment by suggesting that one theory is best fit to answer the question of the morality of the institution of punishment, while another theory is best able to answer questions of how particular punishments ought to be meted out to offenders (Rawls 1955; Corlett 2006).

A third question regarding punishment is the extent to which it might serve to the betterment of just political institutions. The role that punishment might play in maintaining and strengthening just political institutions has been addressed in a myriad of ways in recent years,
especially in the debate about the morality of the very
institution of punishment. It has been argued by punish-
ment abolitionists that punishment is morally wrong
because of social and political inequalities of opportunity
that make the imposition of the punishment unfair and
hence unjust. Indeed, they argue, there exist significant
degrees of unfairness in terms of racism and classism
in the system of punishment that make punishment unjusti-
ified. Proponents of punishment argue that the system
is often fair enough to justify the punishment of those who
truly commit their crimes and are sufficiently responsible
for them, assuming that adequate due process of law
obtains.

Considering the nature of punishment as hard treat-
ment, there are two main theories of punishment—that
is, of the moral justification of the institution, particular
forms, and the role of punishment. Although there are
various hybrid forms of these theories, the two are called
“utilitarianism” and “retributivism.” The former was
defended by Jeremy Bentham ([1789] 1948), among oth-
ers, while the latter was formulated by Socrates (Cooper
and Hutchinson 1997) and later made famous by Im-
manuel Kant ([1780] 1996). Each theory defends some
form(s) of the principle of proportional punishment. While
Bentham provides no fewer than thirteen principles
of proportional punishment based in utilitarian reasoning,
Kant and other retributivists subscribe to some notion
that punishments ought to fit the crimes and that the
choice of punishment does not depend solely on consid-
erations of social utility.

More recently, retributivists such as Joel Feinberg
have argued for a number of expressive functions of pun-
ishment: authoritative disavowal, symbolic nonacquies-
cence, vindication of the law, and absolution of others
(Feinberg 1970). It would seem that these expressive
functions are consistent with either a utilitarian or retributivist
outlook.

Perhaps the most oft discussed issue of punishment is
that of capital punishment. Some capital punishment
abolitionists argue that the criminal justice system is so
corrupted because of racism and classism that the admin-
istration of capital punishment is unfair and hence uneth-
ical. Others point to the prohibitive cost of imposing the
penalty as well as the mitigating factors that seem to
accrue with every capital case. Still others point to the
intrinsic value of human life and argue that this prohibits
the taking of life in any circumstances. Utilitarians who
oppose capital punishment argue that it fails to deter vio-

cent crime and robs society of the opportunity to rehabi-
itate capital offenders (Corlett 2006).

However, proponents of capital punishment argue
that while these considerations are important and ought
to be taken seriously by anyone thinking about punish-
ment, it is unclear that the racism, classism, and other fac-
tors that make capital punishment unfair in one society
make it necessarily unfair when imposed in another that
lacks such factors. Also the administration of capital pun-
ishment can be made more economically efficient without
threatening due process considerations of appeals and
related factors necessary for a reasonably just legal system.
Moreover considerations of alleged intrinsically valuable
human life (in some absolute sense), deterrence, and reha-
bilitation each admit of dubious foundations apart from
particular ethical standpoints, which themselves need
independent argumentative support. In particular, it is
argued, they do not seem to be able to account well for
considerations of deservedness and proportional punish-
ment, without which no theory of punishment can be
properly construed as plausible.

For some, capital punishment is morally justified to
the extent that it is administered without prejudice as to
ethnicity, sexuality, and socioeconomic class and to the
extent that the alleged offender is guilty of the capital
offense; performed it with sufficient intent, voluntariness,
and knowledge; and was at fault in what he or she did,
failed to do, or attempted to do. That some are wrongfully
charged and even convicted and sentenced to death in no
way logically discounts the rightness of capital punish-
ment for those who are guilty. However, no theory of pun-
ishment ought to take lightly the unforgivable evils of
wrongful convictions—especially in capital cases. Thus
these theorists desire to put in place legal rules punishing
those responsible for wrongful convictions, where fault
accrues.

But retributivism and utilitarianism differ from one
another in other ways. According to utilitarianism, pun-
ishment is an evil and can only be justified insofar as it
increases the overall happiness of society—either by deter-
rence of future harmful wrongdoings or by rehabilitation.
Classic criticisms of this position on punishment’s justifi-
cation include that it fails to take into consideration what
offenders deserve and thus minimizes if not nullifies per-
sonal and social responsibility for harmful wrongdoing. It
is future oriented.

Retributivism, on the other hand, holds that harmful
wrongdoers ought to get what they deserve in approxi-
mate proportion to their harmful wrongdoings caused to
others. Classic concerns with this theory include that it
does not clarify the allegedly primitive notion of desert
and that it cannot provide an adequate account of propor-
tional punishment. Those who defend retributivism have
replied with robust conceptual analyses of the concepts of
desert and proportionality, adding that any plausible the-
ory of punishment must take seriously deservedness, pro-
portionality, and responsibility (Corlett 2006). And
insofar as utilitarian theories flounder along these lines,
only retributivism serves as a plausible foundation of punishment’s justification. For any plausible theory of punishment’s justification must make adequate sense of deservedness, responsibility, and proportional punishment because denying the importance of these notions spells disaster for systems of punishment seeking to be just and fair. Retributivism has often been confused with vengeance theories of punishment. But as Feinberg (1965) and Robert Nozick (1981) have argued at some length and with precision, retributivism does not entail vengeance of any kind. There are also moral education theories of punishment (Hampton 1984), but they seem not to entail punishment (hard treatment) at all or unwarrantedly assume a version of utilitarianism to justify punishment. Hence they either are not theories of punishment at all or they beg important questions about punishment’s justification.

Of course there are hybrid theories of punishment, especially between retributive and utilitarian theories. Indeed it might well be the case that most theories of punishment amount to some form of hybrid theory, as not even Kant (who many allege founded retributivism) held to a pure form of retributivism, as many believe he did (Corlett 2006).

Punishment theorists have written much on the matter of forgiveness, mercy, and punishment. Ought the state to forgive or show mercy to harmful wrongdoers by mitigating or even excusing punishments? Many utilitarian theorists have argued affirmatively to this complex question in that the future results of how society responds to harmful wrongdoers is more important than past harmful wrongdoings themselves. Some retributivists, however, have argued that taking responsibility seriously requires that a criminal justice system not permit the language and emotions of forgiveness to interfere with holding harmful wrongdoers responsible for their actions, failures to act, or attempted actions. The reason for this is that they must get what they deserve—nothing more and nothing less—for harmful wrongdoings they have wrought on others. The value of deservedness, responsibility, and proportionality are so strong for some retributivists that not to take them into account in punishment is to commit a most serious injustice. This implies that forgiveness and mercy have no legitimate place in a reasonably just criminal justice system. And this is true even if the wrongdoer offers a genuine apology. Apology, forgiveness, and mercy are irrelevant to a system of genuine criminal justice, though mitigation and excuse play pivotal roles in such a system where responsibility is, all relevant things considered, not full.

While collective forms of punishment do not take on forms of corporal punishment as in individual human cases, certain collectives can be legitimately held responsible for harmful wrongdoings as a kind of vicarious liabil-

ity (Feinberg 1970; Corlett 2006). But unlike individual harmful wrongdoers, collective harmful wrongdoers are typically fined because they have “no soul to be damned, no body to be kicked” (Coffee 1981). Other forms of collective punishment might include adverse publicity (French 1984).

Among the many contemporary areas of investigation in punishment theory is the question of whether there ought to be similar punishments for both successful and failed crimes. Some have argued that certain theories of punishment demand by implication that they ought not to be punished differently simply because of differences in the consequences of the intended crimes. For insofar as the intentions of the harmful wrongdoers are the same, they ought to be punished similarly. Yet this places such theories of punishment in an embarrassing situation, as the result appears counterintuitive (Feinberg 2003). Others deny this point, arguing that no plausible theory of punishment would ever concede that punishment can rightly accrue to a harmful wrongdoer simply because of considerations of intent; that is, there are no purely anti-consequentialist theories of punishment that are even initially plausible. Thus any plausible theory of punishment must hold that a combination of criminal intent and the consequences of the harmful wrongdoing play roles in determining the just punishment of the criminal.

What is clear is that punishment entails hard treatment, and what justifies it on moral grounds must involve at least notions of deservedness, responsibility, and proportionality. To deny this much is implicitly to embrace claims that result in injustice and unfairness.

Purchasing Power Parity

Purchasing power parity (PPP) is the theoretical proposition that national currencies have the same real purchasing power at home and abroad. This notion is best understood starting from the point at which two currencies trade at par. Suppose that the exchange rate of the U.S. dollar for the Canadian dollar is unity (as was approximately true for a good portion of the early 1970s). If PPP holds, goods and services sold within Canada (quoted in Canadian dollars) will have the same prices as goods and services sold within the United States (quoted in U.S. dollars). Assuming Canadian and U.S. dollars were both accepted as media of exchange, there would be no need to post prices in anything other than “dollars.” And it would not matter which dollars were chosen.

Consider the following thought experiment. Suppose one or a combination of the three variables in the PPP equation—the prices charged by Canadian retailers, those charged by U.S. retailers, or the nominal exchange rate—changes such that Canadian goods become 10 percent more expensive than the same U.S. goods when all prices are expressed in the same units (i.e., a common currency). If so, consumer demand for the now more expensive Canadian goods would rapidly decline to zero.

Purchasing power parity may be thought of as ruling out this possibility. The literature has contrasted two ways in which this happens. First, arbitrageurs would take advantage of the fact that the market has two prices for goods and services of the same quality. Specifically, arbitrageurs would buy the lower priced goods in America and resell them at the 10 percent higher price in Canada. However, the increased demand for goods and services sold in America will pull American prices up while the increased supply of goods and services sold in Canada will push Canadian prices down. Arbitrageurs will continue buying in America and selling in Canada until the prices in the two countries are equal. Some economists argue that instantaneous arbitrage prevents the departure from parity—departures from PPP would never be observed in the real world. The more likely case, however, is that the force of arbitrage would be quick enough that the temporary nature of the deviation would be a fleeting economic event, of minor consequence from a macroeconomic perspective.

The second scenario is that restoration of purchasing power parity takes a long time. During this time, consumers and firms are altering their demand and supply decisions. In the literature that uses the consumer price index to compute deviations from PPP, the amount of time is taken for a deviation of 10 percent to work its way down to only 5 percent—the so-called half-life of the deviation—is somewhere between three and five years. In contrast to the near instantaneous adjustment case, this is glacial and should be expected to put into motion seismic shifts in demand and supply across locations. Yet, we do not see this type of quantity reaction in the data. Large variations in real exchange rates (deviations from PPP) are not associated with large variations in trade balances or the overall business cycle.

Thus, purchasing power parity, one of the most intuitive of economic concepts, fails to hold in practice. Moreover, its failure to hold does not appear to lead to the type of quantity reactions we would anticipate from basic economic principles. These observations raise two key issues. The first issue is the conceptual validity of PPP. The second is the empirical validity of PPP measures relative to the theoretical concept.

The consumer basket of a modern industrialized country contains literally thousands of individual goods and services, and the cost of arbitrage varies significantly across them. When costs of arbitrage such as transportation costs arise, price differences across locations are expected to arise as well. These deviations are referred to as deviations from the law of one price (LOP). For items in the consumption basket that are not traded across countries, deviations from the LOP are expected to be large and may persist indefinitely. The classic example of a nontraded item is a haircut, which requires the purchaser and the seller to be at the same place at the same time. While the haircut is exchanged in this bilateral meeting, the market for haircuts is localized. Contrast this
with heart surgery. Here again, the buyer and seller must be at the same place at the same time. While most major cities have impressive medical centers to meet local demand for high-quality care such as this, people do travel to the markets with the best heart surgeons, sometimes across a vast ocean. The combination of scarcity and high consumer benefit overcomes a large trade cost. Commodities, in contrast, often involve small trade costs and their physical depreciation is slow. This means that buyers and sellers do not have to be in the same place at the same time and inventories provide stocks of supply at or near consumption locations. The general message here is that services tend to be localized in trade while goods are globally mobile. We see these distinctions between goods and services in trade flow data, although the Internet is changing the manner in which some goods and a few services are produced and exchanged. While the PPP exchange rate may be thought of as a weighted average of LOP deviations of the individual items that underlie its construction, there is so much variation across those items that any broad-brushed economic interpretation of the PPP exchange rate are highly debatable.

Currently there are perhaps three or four competing theories that attempt to explain deviations from PPP. The simplest and most enduring explanation for the time series variation in relative prices is sticky prices. We know that the nominal exchange rate varies often by a percent or more over the course of a single day, while many retail prices remain fixed for months on end. This begs the question of why prices are so costly to adjust or why it is not in the firm’s interest to adjust.

If two sellers are physically across the street from one another, we expect the prices of identical goods or services to hold up to a deviation associated with the cost of crossing the street. Otherwise, consumers would never visit the high-price location. Given that we do observe a price differential, we are led to associate the deviation with an impediment to spatial arbitrage. The impediments could take various forms: physical distance, branding, patents, or copyrights.

For example, restaurant menu prices need not adjust continuously in light of what competitors are doing because the menus contain differentiated products. Models of monopolistic competition have been developed to account for price differences across varieties of goods. Here the producer has the ability to charge different prices in the same market even when the cost of providing the different goods is the same.

Price differences could also arise under perfect competition and arbitrage because the cost of providing goods to final consumers involves both shipping costs and the costs of providing goods in the retail outlets. The price of bread in a grocery store must partly defray the cost of labor, capital, and rent borne by the grocer. These costs often differ enormously across locations, particularly when the locations are in different countries. This contrasts starkly with the emergence of manufacturers who sell products online. In this case, everyone pays the same price up to a shipping cost, exactly as the trade cost model would predict.

As models develop in sophistication and the empirical data becomes available to make extensive cross-location comparisons of prices of individual goods and services, we will gain an increasingly clear picture of the reasons for the failure of purchasing power parity to hold at a point in time and over the long run. Inevitably this will involve models that incorporate a variety of goods, services, and market structures. Moreover, the empirical target of the theoretical literature is moving as locations of production and consumption change and as the technology for achieving the exchange of goods and services continues to evolve. Highly accessible introductions to the academic literature on purchasing power parity, the law of one price, international trade costs, and price dispersion in the European Union are, respectively, Rogoff (1996), Goldberg and Knetter (1997), Anderson and van Wincoop (2004), and Crucini, Telmer, and Zachariadis (2005).

PURGATORY

Purgatory comes from the Latin word, purgatio, which means purification, cleansing or expiation. Many religions affirm the need for moral and spiritual purification. Purgatory, though, is chiefly identified with the Catholic doctrine that maintains, first, that some souls after death...
require purification (*purgatio*) before reaching heaven, and second, that the prayers and intercessions of the living can assist souls in purgatory.

The word *purgatory* as such, is not found in the Bible, though variations of *katharsis*, the Greek equivalent of *purgatio*, can be found (e.g., *katharoi*, Matt 5:8, and *katharismou*, 2 Pet. 1:9). Church fathers such as Augustine (354–430) found support for purgatory in 2 Maccabees 12:43–46, a passage (not considered canonical by Protestants) that mentions an expiatory sacrifice offered in the temple to atone for the sins of Jewish soldiers who died wearing pagan amulets. The inference is that there is expiation for some sins after death.

Various Church fathers, such as Gregory of Nyssa (c. 330–395), affirmed a postmortem purgation by “purifying fire” (*tou katharisiou puriou*) based on 1 Corinthians 3:11–15 (some will be saved “only as through fire”). Patristic writers such as Augustine and Pope Gregory I (c. 540–604) also believed that Matthew 12:32 implies that certain sins will only be forgiven in the age to come (i.e., after death).

Under the influence of neo-Platonism, some early Christian writers, such as Origen (c. 185–254), suggested an ongoing purification after death leading to a universal restoration (*apokatastasis*) of all humans (and possibly demons) with God. The local Council of Constantinople condemned *apokatastasis* in 543.

The doctrine of purgatory underwent more systematic development in the West than in the East. As its penitential system developed, Latin theology saw purgatory as the postmortem expiation of the temporal punishment due to sins. According to this theology, temporal effects or “punishments” of sin (e.g., wounds to oneself and others) remain even after the guilt (*culpa*) of sin is taken away by confession. Such temporal “punishments” require penances for adequate purification, satisfaction, or expiation. When the temporal effects of sin have not been purified prior to death, the person must undergo purgatory.

Because penances during the Middle Ages were often severe, the Church offered various indulgences, that is, extrasacramental ways (e.g., prayers, pilgrimages, and almsgiving) for gaining remission of the temporal punishments due to sin. These indulgences were granted by the Church via her access to the “treasury” of the merits of Christ and the saints. The faithful could apply these indulgences to themselves for their own purification or to souls in purgatory by means of suffrage or intercession (*per modum suffragii*).

Although purgatory was often seen as a temporary hell, the Italian poet Dante Alighieri (1265–1321) offered a more positive understanding of the doctrine. In the *Purgatorio*, the second part of his *Divine Comedy*, Dante describes the purifying rather than penal aspects of punishment. The souls ascend “Mount Purgatory” while receiving penances, practicing virtues, and reciting prayers designed to purge the root causes of the seven capital sins. Those in “lower purgatory” are purified of sins or vices related to “love perverted,” namely pride, envy, and wrath. Those in “mid-purgatory” overcome sloth, which is associated with “love defective.” Finally, those in “upper purgatory” are purified of “love excessive,” linked to the sins of avarice, gluttony, and lust. For Dante, the purpose of purgatory is the interior purification of one’s love for God and neighbor before entering heaven.

Only the Roman Catholic Church teaches purgatory as dogma. The Profession of Faith, read before the Second Council of Lyons (1274), distinguished between the souls who go immediately to hell after death, those who go immediately to heaven, and those who die in charity but are cleansed after death by “purgatorial and cleansing penalties” (*poenis purgatorii seu catharteriis*). The Council of Florence repeated this doctrine in 1439 and reaffirmed that sacrifices of the mass, as well as prayers and offerings of the faithful, can alleviate the penalties of those in purgatory. In the wake of the Protestant denial of the doctrine, the Council of Trent, in 1563, upheld the reality of purgatory but warned bishops to exclude from popular sermons “the more difficult and subtle questions” not useful for edification and to prohibit all that belongs to curiosity, superstition, or unseemly gain.

The Catholic Church has never defined purgatory as a specific place. The exact nature and duration of the purgatorial punishments is open to speculation, and some, such as Catherine of Genoa (1447–1510), describe the fire of purgatory as the fire of God’s love. Traditional Catholic theology specifies two forms of suffering in purgatory: the pain of loss (*poena damni*), because of the temporary deprivation of heaven; and the pain of sense (*poena sensui*), experienced by souls in a manner analogous to sensible pain. Whatever suffering the souls in purgatory experience is mitigated by their assurance of heaven once their purification is complete. The common Catholic teaching is that, after the general judgment, there will be only heaven and hell, and purgatory will cease.

The Protestant Reformers of the sixteenth century rejected purgatory as an unscriptural doctrine that obscures the atonement of Christ as the only satisfaction for sin. Moreover, they linked purgatory to “false practices” such as indulgences, private masses, and prayers for the dead.

The Eastern Orthodox churches have prayers for the departed in their liturgies, but they have never defined purgatory as a doctrine. Several Orthodox confessions of faith, such as the original ones of Peter Moghila (1596–1647), the metropolitan of Kiev, and Dositeus (1641–1707), the patriarch of Jerusalem, affirmed the
realization of postmortem purification. Some Orthodox theologians have also posited the existence of two hells, one for the damned and another for those needing further purification. Still others have mentioned a middle state of souls after death (mesi katastasis), where they receive comfort from the prayers of the living. In general, though, Eastern Orthodox churches regard the whole matter as too mysterious for dogmatic formulations.

The Catholic Church continues to teach the reality of purgatory. Vatican II (1962–1965) and the *Catechism of the Catholic Church* (1992/1997), however, limit themselves to general affirmations of postmortem purification through the grace of God (cf. Vatican II’s *Lumen Gentium*, 49 and the *Catechism*, 1030 and 1472).

**PURIFICATION**

The concept of purification, or the ritual cleansing of persons and objects, is found across cultures and religions. It is present in urban and rural settings, in sectarian and secularized societies, and in tribal and multiethnic communities. It has been a sociological feature of human existence from antiquity to modernity, one with an array of behavioral guidelines and consequences.

Purification is associated with two other socio-religious notions: purity and pollution. Purity is linked to sanctity, devotion, and safety; pollution is associated with impurity, irreligion, and danger. Purification is regarded as a means of transitioning from a polluted to a pure state. Personal and group activities are carefully regulated by rules and rites designed to protect and purify individuals, communities, the deity or deities venerated by those groups, and even the world itself from the impurity supposedly caused by pollution. These notions arise from within the context of religious worldviews, and they often have transgressions and demonology as causative factors and penitence and exorcism as resolutionary mechanisms. Modern notions of hygiene, disease, waste products, and environmental contaminants that appear to be reflected in the codes and practices of purity, pollution, and purification bear only an inadvertent correspondence to purification. Purity and pollution are usually not based on physical cleanness and uncleanness, but on holiness and the loss of that state through inadvertent and deliberate violations of socio-religious tenets that renders a believer devotionally impure or polluted, thereby excluding him or her from partaking in the activities of a confessional community.

**IMPLICATIONS**

The ideal of purity, the fear of pollution, and the quest for purification arose from the systemic ordering of the religious world. The problem of pollution became a subcategory of evil because ritual impurity was equated with moral disorder caused by the forces of evil. Thus, the holy had to be protected from defilement. As a result, purity and impurity came to be regarded as opposites within religious settings. There was a rejection of spiritual and physiological conditions regarded as inappropriate. These conditions came to be prohibited completely, and they were to be resolved via purification whenever present. In some religions, such as Zoroastrianism, Judaism, and Islam, prohibitions became codes whose breach, whether intentional or unintentional, causes pollution, which is to be corrected by purification and atonement. In other devotional systems, such as in Polynesian societies, items and actions that were holy became taboo, and any violation of the connection between what is *tabu* and the deities with which these items and actions are associated is believed to bring divine wrath upon the violator, and possibly upon his or her community. In each case, however, the shared notion is that of separation of the pure from the impure, based on a religious dichotomy between the holy and the profane (representing good and evil, respectively).

Also central to understanding purification is a widespread belief that pollution can cross physical and spiritual boundaries through transfer between individuals and objects, all of which would in turn become impure and capable of spreading the pollutant. The human body is
one such domain where transition across a physical boundary creates pollution and requires acts of purification. Hair and nails, while attached to the body, are considered to be pure, as are blood, saliva, semen, and vaginal fluid when inside the body. But all these items are viewed as open to pollution by evil spiritual forces once separated from the body’s protection, and they are all capable of causing impurity in any persons and objects with which contact occurs. Ultimately, therefore, it is not just a single person or item that is involved in the system of purity, pollution, and purification, but rather the entire society and environment in which the believers live.

ANALYSIS

Methodological dilemmas exist in the interpretation of purification rituals. Among the issues involved are cultural relativity, the notion that beliefs and rituals are personal and social phenomena having values and meanings assigned by practitioners, the necessity for interpretations to be based on particular contexts, and attention to the historical contexts in which beliefs and practices developed. For instance, the Hebrew Bible, or Old Testament, preserves an apparent distinction in belief, terminology, and praxes between ritual purity and moral purity. Israelites who were not tabor (pure) because of a deliberate or accidental transgression that had rendered them tameh (impure) could not enter the temple nor have contact with believers, activities, and items relating to the community’s religious life. Purification with water, followed by isolation or at least refraining from contact with other persons and items was one prescribed means by which purity could be reestablished. In other situations, such as the purification of men after skin diseases and women after childbirth, sacrifices of burnt offerings (’olah) and sin offerings (hatta’) necessary for the atonement of sins were associated with the process of regaining purity. So a nexus took place between ritual and moral purity in Judaism. Another historically-based intertwining of concepts is seen in Roman praxis, where lustrare (lustration), which may have originated around the second century BCE as a propriatory rite, came to involve sprinkling with pure water, and so was categorized by Greeks and then Romans as a purification ritual, or katharmon.

Perhaps most important to the study of purification is the variety of functions served. For example, purification and penance are viewed by Zoroastrians as necessary to counter evil, which is believed to function as a pollutant external to the holy. In Jewish, Christian, Muslim, Hindu, and Buddhist belief as well, purification can be used to negate impurity and defilement. But Hindu, Buddhist, and Jain penances, or tapas, do not negate impurity caused by contact with an external pollutant. Instead, they are undergone as a form of repentance. Self-flagellation, a practice among European Christians during the Middle Ages and still performed by Shia during the Muslim month of Muharram, involve acts of suffering intended to provide an expiation of sin and spiritual pollution. Despite the differences, however, all such acts of purification are connected by the intent of ensuring physical and, even more importantly, spiritual purity. Therefore, rites of passage or important transitory stages in the life cycle—such as birth, puberty, marriage, initiation into confessional communities and clerical organizations, and death—came to be associated with purificatory rites, as did individual physiological acts, whether voluntary or involuntary, such as urination, defecation, sexual intercourse, childbirth, menstruation, and sickness.

In certain communities, such as among the ancient Israelites, medieval Jews, and ancient and medieval Zoroastrians, participation in purification was obligatory. Among other groups, such as the ancient and classical Greeks, participation in the system of purity and purification, or miasma, appears to have been at least technically a voluntary one. Yet whether obligatory or voluntary, such systems operated on consensus and coercion, and being regarded as impure often resulted in exclusion from communal life.

SELECT INSTANCES

Often, but not always, purification involves an external cleansing of the person or object, an internal expiation of the person, a period of isolation, and atonement for having become impure. The sequence of events varies, as do the items utilized during the process. The Zoroastrian ritual of barashmun i no shab, or purification of the nine (days and) nights, which is now used only before induction as a magus, or priest, is emblematic of such cleansing. A variety of items have been utilized by different cultures as purificatory agents. Earth (dust), urine, and blood are some purificatory agents utilized by specific communities. Dust has often been employed among Zoroastrians and Muslims as a substitute for water. The blood of a sacrificial bull served to purify Roman men undergoing initiation into the mysteries of Mithras during late antiquity. Smoke via fumigation would be used to purify household items among Jews and Zoroastrians.

Water is the most widely used substance for purification. The Christian practice of dipping fingers into a water basin upon entering a church (now quite infrequent) is a remnant of the custom of purification before prayer. All Muslims, irrespective of gender and age, perform wudu’ (or vuezu’), a washing of the face, hands, and feet prior to entering a mosque. Zoroastrians perform a padyab, or rite of protection by water, by washing all uncovered parts of the body and face before praying at a fire temple. Water, because it symbolizes life and fertility,
is also the purificatory agent used prior to initiation in many religious communities—the Christian baptism is the most widely known example, continuing a Jewish and Gnostic tradition that was followed later by Manicheans and Manichaens. The Zoroastrian sade nahm (simple bath) and the Hindu upanayana (washing) serve similar purposes.

Purification rites using water are performed by orthodox male and female Jews, Muslims, Zoroastrians, Hindus, and Buddhists after sexual intercourse to purify themselves from contact with semen and vaginal fluid. Because water is associated with fertility, such purification may also occur prior to marriage to ensure that the new couple begins life together in ritual and moral purity. A Roman counterpart, the lastration, can also be mentioned in the context of purification before marriage. In Africa, washing a Yoruba bride’s feet before entering the bridegroom’s home is another such purification.

Menstruation and childbirth are two situations in which purification is widespread across cultures. The seclusion of menstruating women and the prohibition of sexual intercourse during menses and for a certain period of time thereafter (the time of menses plus one day for Zoroastrians, menses plus four days among Hindus, between three and ten days for Muslims, and seven days for Jews) has been practiced in order to ensure that the husband or male partner does not become polluted by the woman’s ritual impurity. After childbirth, a period of separation or isolation of the mother is prescribed by many confessional groups—it would last for forty days among Jews, Zoroastrians, Hindus, and Buddhists. After menses and childbirth, Jewish women are required to undergo a ritual immersion, or mikveh, to regain purity, Zoroastrian women have to perform a sade nahm, and a ritual bath, or ghul, is undergone by Muslim women. Only orthodox or orthopractic women follow the stipulations completely now. Most other Jewish, Muslim, and Zoroastrian women now regard menses, childbirth, and the blood associated with these conditions as merely physiological processes that have no moral connection, and so they simply bathe or shower in water as they would to routinely clean themselves. The Christian practice of churching—or reintroducing a new mother to the community after childbirth, isolation, and purification—has fallen into disuse.

Fears that sex, procreation, and menstruation were linked to evil and sin reinforced the concepts of impurity associated with them, generated gender-specific misogyny in beliefs and practices directed at women, and contributed to patriarchy in many ancient and medieval societies. Traditionalist communities in both Western and Eastern countries continue some of those dichotomies. One result, among orthodox Jews, Christians, and Zoroastrians, is the exclusion of women from the priesthoods.

Class and caste hierarchies were shaped in part by issues of purity, pollution, and purification as well. One example among Hindus, Buddhists, and Zoroastrians pertains to families that wash and transport corpses, and thus are often shunned as ritually impure due to their occupation. For Hindus, in particular, the varnashrama dharma, or system of endogamous classes, excludes persons who deal with corpses, bodily fluids, and bodily excrements in their work. Those individuals—called dalit (downtrodden), and more paternastically harijans (children of the god Hari Vishnu)—have traditionally been social outcasts living apart from the other classes and unable to worship at temples. Any member of the three upper socioreligious classes—the Brahmins (priests and scholars), the Kshatriyas (warriors and politicians), and the Vaishyas (merchants, artisans, and landowners), all of whom are regarded as “twice born” and therefore permitted to study scripture—who has direct or indirect contact with an untouchable person, through touch, food, water, objects, or even the outcaste’s shadow, becomes polluted. He or she is technically required to undergo a ritual bath for religious purity to be regained. Only in modern India (after 1949–1950) and Pakistan (after 1953) have secular national constitutions deemed the still fairly widespread practice of untouchability illegal.

CONCLUDING OBSERVATIONS

Vitiation of the efficacy of purification is thought to occur if the prescribed rites are not performed exactly or if contact occurs again with impure persons and objects. Consequently, during antiquity and medieval times, the proper performance of purification rituals, specialization of individuals as purifiers, and an extensive literature on purification developed, as evidenced by the biblical Leviticus and the Iranian Videvdad. The violation of divine commandments and contact with evil spirits were said to be the ultimate sources of pollution. As a part of religion, purification was an important, widespread, socioreligious factor linked to good, evil, demonology, and even differential gender and class relations. Its sway began to attenuate slowly in Europe with the Enlightenment and the Industrial Age. From the eighteenth century onward, colonialism spread Western science, especially in connection with medicine, to other societies via secular education. As result, practices of purification have attenuated in the daily lives of many secularized women and men.

PUTIN, VLADIMIR
1952–

With the end of the Cold War and the collapse of the Soviet Union in 1991, Russia’s international relevance ebbed. Consequently, Putin’s presidency has been dominated by domestic concerns, such as the concentration of wealth and power in the hands of the new Russian entrepreneurial oligarchs and separatist violence in the province of Chechnya. The former problem arose when young Russian businessmen, taking advantage of a weak legal system that lacked adequate property rights and could not protect contracts, amassed huge amounts of money and influence in the 1990s when the Russian government began auctioning state-owned assets. Putin, in a crackdown on corruption and illegal business practices, embarked on a crusade against the “robber barons,” resulting in the high-profile and controversial arrest of Mikhail Khodorkovsky, the head of the oil company Yukos, as well as the indictments of many others. While these attacks on Russia’s megarich may have broken the power of the oligarchs, they have drawn criticism for leading to the consolidation of power in Putin’s hands and the suppression of media outlets critical of Putin’s administration.

The problem of Chechnya has plagued Russia since the first Chechen war began in December 1994. The first war ended in 1997 with a peace treaty that was violated when Chechen separatists invaded the neighboring Russian republic of Dagestan to consolidate power and establish Islamic rule. But the invasion and the subsequent bombing of buildings in Russian cities, allegedly by Chechen rebels, had a galvanizing effect on Russian public opinion, which simultaneously discredited Yeltsin’s administration and strengthened Putin’s image as a strong nationalistic leader, contributing to Putin’s victory in the presidential elections in March 2000. By the end of 2006, the Russian military occupied much of Chechnya, but Chechen rebels had carried out several brutal attacks against civilian targets, including the seizure of a Moscow theater on October 23, 2002, which resulted in the deaths of 130 civilians, and the siege of a school in Beslan on September 1, 2004, in which 344 people, including 186 children, were killed.

While Putin’s legacy in Russian politics remains unclear, he is trying to reestablish Russia’s place on the world stage and to shepherd Russia through difficult political and economic transformations. Putin enjoys personal relationships with many Western leaders, including U.S. president George W. Bush, French president Jacques Chirac, and British prime minister Tony Blair. While Russia has been accommodating toward the West on issues such as counter-terrorism, other concerns such as domestic civil liberties have strained those connections. Putin has come under fire from Western observers for stepping back from Yeltsin’s democratic reforms and moving Russia toward a semi-authoritarian regime. This domestic retrenchment has been accompanied by a halting rapprochement with the West, including acceptance of NATO’s expansion into central Europe and the Baltic states, and gradual economic improvement. However, having failed to diversify Russia’s domestic economy, the country’s economic success rests mainly on the export of oil, casting doubts on the long-term viability of Putin’s
reform plan. Critics fear that ultimately Putin’s failure to enact meaningful political reform will undermine Russia’s economic future as well.

PUTNAM, ROBERT
1941–

It has been a fundamental concern of the social sciences to understand the individual, societal, and governmental traits that enable a human community to thrive. The research of Robert D. Putnam is driven by a desire to understand the conditions for effective governance. Putnam has examined the question of how national traditions of ideological style affect political decision-making in books such as The Beliefs of Politicians (1973) and Bureaucrats and Politicians in Western Democracies (1981). In Hanging Together (1987) and Double-Edged Diplomacy (1995) he also looked at how political leaders negotiate within the constraints of domestic political opinion and national interest to develop international agreements that are beneficial to all signatories.

Putnam is best known, however, for his work on the ways in which an active community—one characterized by a high level of social capital—contributes to the welfare of society and the effectiveness of government. Following Putnam’s lead, the Organisation for Economic Co-operation and Development (OECD) and the World Bank have each issued reports on how social capital can assist economic development in sub-Saharan Africa, East Asia, and eastern Europe. As Putnam noted wryly in the epilogue to his book Bowling Alone (2000), he went overnight from being an “obscure academic” to being a guest of presidents and prime ministers and appearing on talk shows and in the pages of People magazine.

In Bowling Alone Putnam defines social capital as “social networks and the norms of reciprocity and trustworthiness that arise from them” (p. 19). Like financial, physical, and human capital, stocks of social capital can be built up or drawn down. Putnam finds that the accumulation of social capital in America is rapidly dwindling. His metaphor for the reduction of organized social networks, that Americans are now “bowling alone,” is emblematic of their reduced willingness to engage with others for purposes ranging from community improvement to pursuing a hobby.

Putnam’s first sustained treatment of the effects of social capital centered on Italy. Despite the equalization of financial resources available to Italian regional governments, some are far better than others in developing effective policies. Putnam discovered that those regions with a high level of social capital—including active participation in politics, widespread feelings of solidarity, trust and tolerance, and a social structure rich in associational life—enjoy more effective governance because they create an active partnership between government and society. Where social networks are widespread, Putnam notes in Making Democracy Work (1993, p. 113), “light-touch government is effortlessly stronger because it can count on more willing cooperation and self-enforcement among the citizenry.”

Putnam’s work in Italy led him to consider declining social capital in the United States. Over the last generation, America has experienced sharp declines in citizen participation in politics, in active membership in all manner of clubs and associations, in church membership and attendance, in involvement in unions and professional associations, and even in social gatherings and family dinners. We have become a spectator society, more likely to support community purposes through our checkbooks than through direct involvement. In Democracies in Flux (2002), Putnam and his colleagues found that other countries have also experienced declines in social capital. The United States is distinctive because the loss of connectivity and participation began earlier and has been steeper than elsewhere.

The immediate impact of a growing disconnection among family, friends, and neighbors is to reduce the quality of social and political life. Growing levels of political distrust and alienation, declining satisfaction with one’s life, the physical decay of cities, and increases in crime, teen pregnancy, and mortality rates are all associated with diminishing social capital. As Putnam notes in Bowling Alone, “Weak social capital fosters the symptoms of social disintegration, such as crime and poverty, and those symptoms in turn further undermine social connections” (p. 287).

Critics have pointed out that the concept of social capital levies a special responsibility to understand social networks in poor communities, and for that matter in any community not organized in ways characteristic of predominantly white, middle-class neighborhoods. The constraints of income, leisure, and social amenities make it likely that poor communities will lag in social capital for-
mation compared to wealthier areas. There are alternative forms of social organization in poorer communities, though, and understanding social capital formation in such areas requires an appreciation of forms of association and collaboration that may be quite different from those characteristic of middle-class communities. Cultivating a broad understanding of social capital formation has always been an objective of Putnam’s, implied in his juxtaposition of reading clubs with bowling leagues as two effective forms of association.

Some observers have pointed to a “dark side” of social capital. A tightly knit community is a community of control. When you know the religion, ethnic background, and political beliefs of everyone in your neighborhood, and when your neighbors know yours, there is pervasive pressure for homogeneity. One who does not (or cannot) conform remains an outsider. The same social networks identified by Putnam as creative of social capital—churches, clubs, social and civic organizations—are identified by Antonio Gramsci as structures that maintain the hegemony of the dominant group (Gramsci 1971).

Although communities with tightly knit social networks may be less tolerant, it is possible to combine highly developed social networks with collaborative attitudes toward people outside those networks. This is a phenomenon Putnam calls the “bridging” form of social capital. In Better Together (2003) Putnam recounts a number of strategies community leaders use to develop community networks that form bridges over existing social divides.

Given the significance of social capital for human welfare, it is important to know how stocks of social capital can be increased. Putnam’s work on Italy demonstrated that regional variations in social capital remained strikingly similar for over 800 years, despite massive changes in government, society, and economy. His more recent work on the United States, however, emphasizes the positive effects of people’s efforts to organize on behalf of some cause that will improve their lives. People do not set out to build social capital, but trust and social networks are nonetheless created as a by-product of person-to-person contacts that occur in the process of working for a common goal. Trends in social capital, like trends in financial or human capital, feature growth sectors even in a general context of stagnation or decline. Robert Putnam’s work aids in the identification of what concerned citizens can do to increase the extent of interpersonal connectivity and trust in their societies.

PUTTING-OUT SYSTEM

The putting-out system was a system of domestic manufacturing that was prevalent in rural areas of western Europe during the seventeenth and eighteenth centuries. It evolved out of an early form of independent commodity production, constituting a transitional phase to what German social theorist Karl Marx (1818–1883) called the “formal” subordination of labor to capital.

The subordination of labor to capital refers to a situation in which the direct producers are separated from the means of production, depending on capitalists to provide them with the necessary tools, machinery, and raw materials to produce commodities. Such producers also receive a wage from the capitalists and have no control over the disposition of the products of their labor. Wage-earners

Putting-Out System

642 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
who still retain considerable control over their own labor process, however, are subject merely to “formal subordination” rather than to the “real subordination” to capital that characterizes the fully developed factory system of industrial capitalism.

Domestic workers involved in the putting-out system typically owned their own tools (such as looms and spinning wheels) but depended upon merchant capitalists to provide them with the raw materials to fashion products that were deemed the property of the merchants. Semi-finished products would be passed on by the merchant to another workplace for further processing, while finished products would be taken directly to market. The typical commodity product of the putting-out system was cloth (more specifically, wool textiles), although other commodities (notably ironware) were also produced under this system.

A salient feature of the putting-out system was the high degree of control that the direct producers retained over their own labor processes. Working at home (or near home) and at their own pace, domestic producers were well positioned to balance work-time and leisure-time in accordance with the pre-capitalist preference for leisure. The system also allowed adult family members to develop a domestic division of labor in which their children could contribute productive labor under direct parental supervision. These circumstances were conducive to the rise and consolidation of the nuclear family as a dominant family form—a form that was also encouraged by the earlier (and still-extant) system of independent commodity production.

With time, it became clear to the merchant “putters-outs” that their domestic employees required a greater degree of supervision to maximize their productivity and discourage “embezzlement” of raw materials or even finished products. Stephen Marglin argued in his 1974 article “What Do the Bosses Do? The Origins and Functions of Hierarchy in Capitalist Production,” that it was these social considerations rather than any technological imperative that accounted for the rise of the factory system. By removing wage-earners from their own domestic environments and assembling them in a common workplace, merchant capitalists were in a better position to control the hours and pace of work and, through vigilant surveillance, to prevent embezzlement. By doing this, of course, many merchant capitalists transformed themselves into industrial capitalists, inaugurating the long transition to a “specifically capitalist” as opposed to an artisanal mode of commodity production.

Dan Clawson argued in his 1980 publication Bureaucracy and the Labor Process that Marglin’s “social control argument” for the disappearance of the early putting-out system and the rise of the factory has many strengths but is one-sided in its dismissal of the important role played by new technologies (especially power-driven machinery) in facilitating the subordination of labor to capital. According to Clawson “It is much more fruitful, and obviously the only Marxist approach, to understand the process as one of class struggle: Capitalists tried to impose social control in the form of factories, while workers struggled to resist. In this struggle, technological innovations were crucial capitalist weapons to help change the balance of power” (p. 51). Furthermore, noted Clawson, by assembling workers in large factories and workshops, capital could significantly improve their productivity by imposing ever-more detailed divisions of labor and taking advantage of machinery requiring a central power source.

The putting-out system all but disappeared in western Europe by the nineteenth century. However, by the late twentieth century it experienced a revival, stimulated by the advent of new computer and information technologies. Thanks to computer technology, the Internet, and new systems of inventory control, it has become increasingly possible for capital to employ stay-at-home workers without sacrificing productivity, control over hours, or effective cost accounting. The products of this new putting-out system are varied, but its most typical product is information.

PYGMALION EFFECTS
The Pygmalion effect, which is an interpersonal form of a self-fulfilling prophecy, borrows its name from the myth by the Roman poet Ovid and the subsequent play by George Bernard Shaw. Pygmalion was a sculptor who carved a sculpture of a beautiful woman from a piece of flawless ivory. He fell in love with his creation and begged the goddess Aphrodite to intervene on his behalf. She was so moved by his devotion that she brought the statue to life, and they lived happily ever after. In social psychology, Pygmalion effects occur when one person’s beliefs or expectations about another creates or elicits the expected behavior, much as Pygmalion created his perfect woman, or Professor Higgins transformed Eliza Doolittle into a lady in Shaw’s play.

Psychological research on Pygmalion effects began with Robert Rosenthal’s studies that showed that experimenters’ expectations for their participants’ behavior could operate as self-fulfilling prophecies. Self-fulfilling prophecies were first defined by Robert K. Merton (1948) as originally false definitions of the situation that evoke new behaviors that make the false definition come true. In a research context, this means that experimenters may obtain significant results not because their theories are correct, but because they unintentionally bias participants to respond in the hypothesized manner. For example, Rosenthal and Kermit Fode (1963) showed that rats whose experimenters believed them to be specially bred to be “maze bright” actually completed a test maze more quickly than rats believed to be “maze dull,” although in reality the “maze bright” and “maze dull” labels had been randomly assigned.

These studies initially generated tremendous controversy because they raised the inevitable question of the extent to which research findings are merely an artifact of experimenter bias. Sufficient studies were conducted to confirm that experimenter expectancy effects can and do occur and that, consequently, steps should be taken in the design of experimental studies to prevent them. The simplest way to do so is to conduct a study in a double-blind manner, such that neither the participant nor the experimenter is aware of the participant’s experimental condition. Today, the double-blind randomized experiment is considered the gold standard of experimental design.

Rosenthal and his colleagues then turned their attention to other domains where Pygmalion effects could be operating. In 1968 Rosenthal and Lenore Jacobson published *Pygmalion in the Classroom*, describing the results of an experiment in which teachers at an elementary school were informed that certain of their students had performed well on a test of “academic blooming” and could be expected to demonstrate dramatic spurts in academic performance in the upcoming school year. In reality, the students identified as “academic bloomers” had been randomly chosen. Results of IQ tests administered at the end of the school year showed, however, that students labeled “academic bloomers” did in fact demonstrate significantly greater gains in IQ across the school year compared to control students. This finding similarly generated tremendous controversy, owing to the inescapable implication that some children who do not thrive in school may underperform not because of limitations in natural ability but because their teachers do not expect them to do well. This implication is particularly socially problematic when one considers that teachers’ expectations are not random, but are systematically related to the socioeconomic status and race of the students.

The controversy was laid to rest in 1978 when Rosenthal and Donald Rubin published a meta-analytic review of the 345 studies of Pygmalion effects conducted to date. This review showed, first, that the combined significance level for Pygmalion effects was highly statistically significant across all studies and, second, that the average effect size was a Pearson correlation coefficient of $r = .33$, an effect considered to be moderate in magnitude. The Rosenthal and Rubin review thus provided definitive evidence that Pygmalion effects occur across a wide range of domains and are of practical importance.

Subsequent research on Pygmalion effects has been concerned primarily with documenting their existence in other interpersonal contexts, including everyday interactions and the workplace, and with understanding their underlying mediating processes—in other words, identifying the specific verbal and nonverbal behaviors given off by expecters that elicit the expected behavior from the targets. For example, Mark Snyder, Elizabeth Tanke, and Ellen Berscheid (1977) showed that men spoke in a warmer and friendlier fashion during telephone conversations with women whom they had been led to believe were very attractive, which in turn elicited warmer, friendlier, and more appealing behavior from the women.

Efforts to eliminate Pygmalion effects have been largely ineffective, owing to the fact that the behaviors that cause these effects are often subtle and not under the conscious control of the expecters. Future research needs to focus more on ways in which we can harness the power of positive expectancies and minimize the destructive effects of negative expectancies.

Monica J. Harris
Muammar al Qadhafi was born in 1942 to a nomadic Bedouin family, which was part of the Qadhafa tribe. After completing his primary education, Qadhafi attended the Sebha secondary school in Fezzan, Libya, between 1956 and 1961, where he received a traditional Islamic religious education. The political events that took place during his school years—including the establishment of Israel and the defeat of the Arab armies and Gamal Abdel Nasser's (1918-1970) rise to power in Egypt—defined the fundamentals of his political philosophy and worldview. Likewise, his tribal background and Islamic education contributed to his piety and the high value he attached to family ties, egalitarianism, and personal honor.

Between 1961 and 1963 Qadhafi attended the University of Libya after which he joined the Military Academy in Benghazi, which was opened to members of low income classes and offered them an opportunity for upward economic and social mobility. During his stay at the military academy, together with a few of his fellow cadets Qadhafi formed a free officer movement, which four years later would depose the pro-western Libyan monarchy. After his graduation from the academy in 1965, he was sent to Britain for one year of military training at the Royal Military Academy at Sandhurst.

On September 1, 1969, in a bloodless coup, Qadhafi and a group of seventy young army officers seized control of the government and overthrew the Libyan monarchy. The coup received enthusiastic backing from the Libyan people and the army. The Revolutionary Command Council abolished the monarchy and proclaimed Libya as the Libyan Arab Peoples Republic.

QADHAFI'S POLITICAL IDEOLOGY AND FOREIGN POLICY

While Qadhafi occupied the position of head of state and the commander-in-chief of the armed forces, he left the day-to-day administration of governmental tasks to his subordinates and devoted his time to his revolutionary views concerning pan-Arabism, Islam, and the struggle against pro-western Arab reactionary forces, imperialism, and Zionism (including support of the state of Israel). Official government statements and the Libyan press referred to Qadhafi as the “Brother Leader,” “Guide of the Revolution,” and “Philosopher of the Revolution.”

Instead of using socialism or western liberalism, Qadhafi gave primacy to his own vision of Islamic socialism and pan-Arab Nationalism. He called his form of government a “direct, popular democracy” and “Islamic socialism.” He formed public committees to increase the opportunities for the Libyan people to exercise direct political participation and supervision of the government.

In 1973 Qadhafi proclaimed his Third Universal Theory, which consisted of socialism, popular democracy, Arab unity, and progressive Islam. His political philosophy appeared in his 1976 Green Book. Qadhafi called for the nationalization and redistribution of domestic industries and large private landholding, including religious properties. He also imposed a system of Islamic morals and outlawed alcohol and gambling. He directed the pub-
lic committees to supervise the mosques in order to undermine the influence of the clerics who were critical of the Green Book and his nationalization of private property.

Qadhafi advocated Arab and pan-Islamic unity and tried unsuccessfully to form unions with other Arab states including Egypt, Syria, and Tunisia. He has also been active in African politics and various pan-African organizations, and he has given extensive humanitarian aid to African states.

QADHAFI'S SUPPORT OF REVOLUTIONARY MOVEMENTS AND TERRORISM

Qadhafi also extended financial and military support to several liberation and opposition movements such as the Palestine Liberation Organization, Black September (another pro-Palestinian organization), and the Irish Republican Army (IRA) among others. His revolutionary committees were engaged in the assassination of some Libyan dissidents living abroad. By the mid-1980s he was widely regarded in the West as the key supporter of international terrorism.

In an attempt to force Qadhafi to abandon his support of terrorist groups, in March 1982 the United States declared a ban on the import of Libyan oil and the export to Libya of American oil technology. During January and March 1986, President Ronald Reagan (1911–2004) ordered the American navy to attack Libyan patrol boats, and on April 15, 1986, he directed the American air force to attack Qadhafi’s headquarters in Tripoli and Benghazi. The United Nations also imposed upon Libya economic sanctions for Qadhafi’s refusal to allow the extradition to the United States or Britain of two Libyans accused of the bombing of Pan Am Flight 103 over Lockerbie, Scotland, in December 1988.

QADHAFI'S ECONOMIC EXPERIMENT FALTERS

The 1990s witnessed increasing disapproval of Qadhafi’s revolutionary experiment by Islamic clerics, the middle class, professionals, and students. Moreover, the Libyan economy experienced serious problems resulting from the international sanctions, the decline in the price of oil in the second half of the 1980s and the 1990s, and poor government economic planning. This economic downturn limited the capacity of the government to provide employment and social welfare benefits to the politicized youth and the urban poor. The economic crisis was made worse by the fact that half of the Libyan population at the time was below the age of 15.

Following years of international isolation and growing socioeconomic challenges, and despite the anti-imperialist rhetoric against the West, Qadhafi’s revolutionary ideals did not come to fruition. Not only did his Arab unity schemes fail, but also the various armed revolutionary movements he backed did not achieve their goals, and the demise of the Soviet Union left Qadhafi more vulnerable to his main archenemy, the United States.

In the wake of these developments, Qadhafi began to redirect Libya’s domestic and foreign policy starting the second half of the 1990s. He initiated economic liberalization measures to revitalize the economy and to attract foreign capital and investments. In his effort to lift the United Nations sanctions, in 1999 Qadhafi pledged to fight Al-Qaeda and offered to open up Libya’s weapons program to international inspection. Through the mediation of South African president Nelson Mandela, Qadhafi gave up the two accused Libyans for the bombing of Pan Am Flight 103 in order to be tried in the Netherlands. In August 2003 Libya formally accepted responsibility for the Lockerbie bombing and Qadhafi agreed to pay compensation of $2.7 billion to the families of the 270 victims.

The terrorist attacks of September 11, 2001, availed Qadhafi the opportunity to further normalize Libya’s relations with the West. Qadhafi condemned the attacks and extended his condolences to the American people, and he supported the United States’ right to retaliate. As a sign of his abandonment of supporting international terrorism, Qadhafi started sharing information about Al-Qaeda and other terrorist groups with British and American intelligence services. In 2003 he allowed international inspectors to dismantle Libya’s weapons of mass destruction. Because of Qadhafi’s moves, the UN sanctions were lifted, and in March 2004 British prime minister Tony Blair became the first western leader in decades to visit Libya to meet with Qadhafi.

QUALIFICATIONS

In any society where good (desirable) jobs and high social status positions are relatively scarce, elites put mechanisms into place to limit access. Whereas in traditional societies "proof of ancestry" served that gatekeeper function, in modern societies the gatekeeper mechanism is expected to be the system of qualifications. The German social theorist Max Weber famously noted the rise of education, and specifically certificates (diplomas), as the preeminent form of qualification in modern society. In delineating the distinction of a society/system dominated by bureaucratic form (as opposed to traditional or charismatic forms), Weber wrote that office holding in bureaucracy was a vocation that required at least a prescribed course of training and working experience and oftentimes specialized examinations. The system of examinations was, then, a way to ensure the qualifications of any applicant (of any social strata), and it took the place of the traditional selection by noble birth.

EDUCATIONAL CREDENTIALING

The sociologist Randall Collins, studying U.S. society closer to the turn of the millennium, noted that education and parent occupational level were indeed the most important predictors of occupational success. Yet Collins, in the influential book *The Credential Society: An Historical Sociology of Education and Stratification* (1979), challenged the notions that (1) education led to skills acquisition and that (2) skills were the main determinant of occupational success. Instead Collins posited that while educational credentials were still the key to occupational achievement, this correlational path need not, and often did not, run through the intervening variable of skills acquisition. Collins noted that most skills could be learned on the job, but the best jobs were saved for the applicants with the best educational credentials. This line of thinking was presaged by the work of postwar French sociologists such as Georges Friedmann (1946) and Alain Touraine (1955) who claimed distinctions between the concepts of qualification (a social construction with historical specificity) and skill (job-specific mastery). Touraine was particularly concerned with how the Industrial Revolution increasingly caused "social" qualifications to replace technical competence as measures of worker value.

Support for the value of education as one of these new qualifications was also proffered in economics by the Nobel laureate A. Michael Spence. Spence argued in 1973 that in a (labor) market characterized by imperfect information, individuals possessing qualifications would need to signal such qualifications to potential employers. Spence noted that education worked as a signal of qualification in the labor market. Taken together, the arguments of Collins and Spence suggest that whether or not education actually bestows qualifications, it bestows the presumption of qualifications in a competitive labor marketplace. As such, it is often not the actual possession of qualifications that leads to a job but rather a credential or signal of employability that leads to a job. That such credentials or signals are not equitably accessible by all members of a given society has been a continuing source of social science inquiry and popular consternation.

Historically, in societies stratified by race, gender, and class, educational credentialing has stratified correspondingly. Human Rights Watch concludes that children across the globe face discrimination in access to education, and thus the educational imparting of qualifications, based on race, ethnicity, religion, and other status. A 2003–2004 UNESCO report confirms that gender disparity in education remains a deep concern for much of the developing world. This concern is exacerbated in societies that are increasingly characterized by the need for knowledge and technological expertise acquired through education.

Yet in many Western postindustrial societies, gender parity in access to education (and even higher education) has been largely achieved. While women in these societies have made great strides in educational credentialing, racial minorities have fared slightly less well, and lower social classes still less well, even though progress has been made. For example, racial discrimination embedded both inherently in a qualification vehicle and in that qualification's use as an exclusionary moving target was addressed...
Quality Controls

directly by the Supreme Court of the United States in 1992. The U.S. Supreme Court, in United States v. Fordice, 505 U.S. 717 (1992), noted that the State of Mississippi had used minimum ACT test scores first as a way to racially segregate institutions of higher education and then, as black student scores on these exams rose, as a way to maintain segregation by setting minimums out of reach of even the highest performing students of color. In striking down Mississippi’s sole dependence on a discriminatory qualifier, the court further noted that most other states used a variety of qualifications in order to compensate for discrimination embedded in any one indicator and thereby improve racial balance on higher education campuses. The case demonstrates both the progress made and the barriers still to overcome in the United States’ use of qualification for selection purposes.

OPPORTUNITY AND OCCUPATIONAL OUTCOMES

But even if women and racial minorities (though not necessarily lower and working classes) increasingly have access to qualifications (taught skills or merely credentials) afforded by attendance at both non-elite and elite colleges and universities, there is still evidence that coveted jobs are not meted out by qualifications alone. Indeed, social capital theorists are quick to point out that many individuals may share the same qualifications (or human capital) when seeking jobs yet may not achieve the same occupational outcomes due to the scarcity of opportunities. Groundbreaking research by Mark Granovetter in 1974 empirically confirmed the common wisdom that in job placement, it is often not “what you know” (formal qualifications) but rather “who you know.” Even in postindustrial, bureaucratized societies, then, traditional modes of meting out jobs based on social capital and networks oftentimes negate the value of educational qualifications.

Further, some occupational qualifications depend less on education and training and more on physical or biological traits. In the United States, for example, societal controversies have arisen over the stated qualifications for jobs such as firefighters and police officers: Admittance to these occupations typically entails passing physical ability and strength tests that have often discriminated on the basis of sex. U.S. statutes, such as Title VII of the 1964 Civil Rights Act, that prohibit discrimination in employment based on race, color, religion, sex, and national origin still allow exceptions in cases where an employer can demonstrate that sex, religion, or national origin is a bona fide occupational qualification (BFOQ). British law, under the sex Discrimination Act of 1975, also allows for limited discrimination in recruitment, training, promotion, and transfer in a job for which the sex of the work is a “genuine occupational qualification” (GOQ). As in the U.S. law, the occupational qualification mandating preference for a particular social category exists when the essence of the job makes it unsuitable for persons in other social categories. In these cases, then, sex, religion, and national origin may denote actual job qualifications and not just mark inequitable access to job qualifications.

Due to the richness of the concept, social scientists have been interested in qualifications as both an independent and dependent variable. As noted above, there is a long social science tradition of trying to understand precursors and access to qualifications in the job market (often focusing on racial and gender disparity in possession of job qualifications). As well, newer literature is beginning to center questions of qualifications as independent variables in models of income and occupational prestige, for example. The French sociology of work tradition is a reminder that qualifications are often social constructions, manipulated in the interests of elites. And finally, a continuing challenge is the interchangeability of the constructs of job qualifications and KSAs (knowledge, skills, and abilities) in the management and sociological literature coming out of the United States.

QUALITY CONTROLS

Quality control is a management process that provides information about the conformity of either products or services to prespecified standards of utility. This function first became professionalized during the nineteenth century as a means for addressing the growing problem of the asymmetric distribution of product information that
attended the rise of giant business enterprise and the emergence of mass markets. On the firm level, the growing scale and scope of manufacturing created pressure for the development of new metrics for informing management decision processes. While cost accounting was effective in ascertaining profitability, it provided little insight into the factors that affected output quality. This represented a potentially serious informational shortcoming as the largest manufacturing entities sought the realization of economies of scale through long production runs of standardized products.

On the consumer level, industrialization changed the nature of the relationship between consumers and producers. Unlike the shop economy of the preindustrial era, the line of communication connecting these groups for resolving quality issues became attenuated by the intermediation of longer supply chains and more impersonalized distributional arrangements. Industrialization also displaced indirect modes for assuring quality through guild or craft union validation of artisan skills through apprentice, journeyman, or master status. Many firms following scientific management principles enhanced the efficiency of their production lines by systematizing work effort through worker time-and-motion studies. These initiatives de-emphasized the role of the skilled craft practitioner and encouraged the placement of greater reliance in mass production on cheaper un- or semiskilled labor.

Quality assessment had within its compass the ability to surmount the problems of informational asymmetries about product quality in two ways. First, firms could apply quality standards to define what constituted a steady-state condition in their manufacturing. This new firm-specific knowledge, used in conjunction with accounting and financial data, could enhance efficiency by extending organizational capacities for planning, coordinating, controlling, monitoring, and evaluating production activities. Such study was also important to corporations in determining the economic limits of product inspection. Second, the dissemination of reliable information about product standards helped to eliminate asymmetries in external markets, thus contributing to a reduction in consumer risk perceptions. Such knowledge also helped consumers weigh more objectively the trade-off between performance benefits and costs in project analysis. Moreover, quality standards affected producer reputations by providing consumers with a basis for making grading comparisons between the output of rival suppliers.

Initially the focus of quality assessment centered on products rather than processes. The measurement of key design attributes and their alignment with engineering design standards became paramount. This involved the use of such measurement devices as gauges, calipers, jigs, and meters to determine if products met physical and performance requirements detailed in specification documents and blueprints. Such evaluation also involved destructive testing to measure the physical limits of materials. These early approaches, however, proved insufficient because they lacked an effective means for assessing the significance of test data. The statistical summarizations of this period were mere enumerations, devoid of a scientific basis for defining the nature of quality or for determining whether it had been effectively controlled in production.

The Bell System in the United States achieved a major breakthrough in surmounting problems of quality definition and analysis in the 1920s by developing new approaches that emphasized process and probability theory. The initial focus of innovation centered on the captive manufacturing subsidiary Western Electric, which supplied most of the material requirements of the Regional Bell Operating Companies. Such methodological innovation responded to regulatory pressures to provide more economical and efficient communication services through the deployment of more reliable equipment. In 1925, quality-control research centered on the inspection engineering department of the Bell Laboratories. Prime movers in establishing what became known as “statistical quality control” included Walter A. Shewhart of the theory and special studies unit and Harold F. Dodge of the inspection methods and results unit. Working in close coordination with the firm’s manufacturing departments, they defined a unifying theory and set of applied methodologies that revolutionized quality engineering by 1928.

The assessment of quality at Bell benefited from several new analytical constructs based in probability theory. The control chart, for example, exploited the properties of the normal curve to clarify the economic limits of control. It distinguished between “common causes of errors” that were random and uncontrollable and “assignable causes of error” that could be rectified through management action. The trade-offs inherent in sample selection and evaluation became better illuminated from the specification of consumer’s risk (Type I) involving the incorrect acceptance of an unreliable sample and producer’s risk (Type II) involving the incorrect rejection of a valid sample. Customer planning was facilitated by the determination of the “average outgoing quality limit,” a steady-state metric indicating the maximum number of defects in product shipments. In these and other ways probability theory increased the analytical power, flexibility, and range of quality engineering.

The new knowledge subsequently gained higher professional status in the United States and abroad. Shewhart taught the first collegiate course in quality engineering at Stevens Institute of Technology during the late 1930s, and
soon thereafter Armand V. Feigenbaum of General Electric wrote the first doctoral dissertation on the subject at the Massachusetts Institute of Technology. During World War II, the new techniques were applied extensively in the U.S. Army Ordnance Corps with the assistance of Bell System advisers. W. Edwards Deming was also instrumental in organizing training programs for national defense industries through the War Production Board. In the postwar era, engineers with the Civil Communication Service of Supreme Command Allied Powers helped to revive interest in the topic in Japan. The Japanese Union of Scientists and Engineers began sponsoring courses presented by Deming, Joseph Juran, and others. In 1947 a new professional association, the American Society for Quality Control (now the American Quality Society), was founded. In 1956 the European Organization for Quality Control was formed.

While manufacturing quality control has continued to evolve, the new frontier involves the use of its concepts to address problems of informational asymmetry for services. The U.S. General Accounting Office, for example, reflected a concern about quality in audits of federally financed projects by requiring the evaluation of program effectiveness and results. Studies of environmental pollution, for example, often employ the probabilistic tools initially developed for industry. The notion of quality has also affected professional governance, albeit in a less quantitative way. The American Institute of Certified Public Accountants since the 1980s has required accounting firms to evince compliance with practice-quality standards as a condition of membership.

**QUALITY OF SERVICE**

**SEE Quality, Product.**

**QUALITY, PRODUCT**

The product quality concept is often surrounded by some vagueness. Sometimes it is associated with such imprecise notions as “goodness,” “expensiveness,” “having class,” and “satisfying” (Robson 1986, p. 69), albeit all these notions of quality point to the broad idea of customer satisfaction.

Quality is also sometimes defined as freedom from deficiencies or conforming to specifications, or predetermined standards that remain largely assumptive and imprecise. Because quality is perceived as “freedom from deficiencies,” the concept is often interpreted to mean quality control and thus the exclusive concern of a special unit of the organization that may be called the Quality Control Department.

In recent years, however, a new quality concept has emerged that appears to focus more on product aspects such as utility, functionality, brand, packaging, and after-sales service that meet the needs of customers in a wider way. Quality is perceived as “meeting the requirements of the customer, now and in the future” (Cole 1996, pp. 232, 237–238). The quality concept is therefore often related to the customer, and so in this sense we talk about not only quality of goods but also quality of services such as accounting, invoicing, and communication.

Customers also include internal customers, people in the production line who are supplied with or receive the product of another’s work. The inclusion of internal customers has meant that theoretically as well as practically the quality concept covers those things that affect not only end users, who may not even be seen or known, but everyone involved. Consequently, it becomes incumbent on every worker to meet the requirements of his or her own customer(s).

This new dimension to the quality concept underscores a shift in emphasis from quality control to quality of service, from the culture of “appraise and react” to the prevention of defects. Quality improvement and emphasis on quality concern everyone in the organization, and so reflect a realization of the real importance of quality.

The quality policy of a company that aims at defect-free performance would probably rest on deficiency-prevention programs. Investment in preventing errors involving costs in getting things done right the first time or preventing things going wrong in the first place through proper training of workers, planning ahead, and investing in appropriate tools, techniques, and technolo-
gies can significantly reduce total costs of failure and quality. Theoretically, the economics of quality would probably state that reduction in the number of errors through prevention would tend to lead to reduction in total costs. Consequently, quality as a policy option may be warranted by solid commercial and financial considerations.

Technological changes and innovations have the potential to improve techniques of work, and by preventing mistakes and increasing productivity, a better way of doing work assures product quality. Other prevention activities capable of changing quality include monitoring worker efforts and efforts aimed at improving managerial quality or skills. Because the organization depends on the skills, knowledge, innovativeness, and motivation of workers, improved managerial skills and quality can integrate and align employee contributions with organization strategy for achieving results, increase problem-solving capacity, provide understanding and use for information systems to support decision-making and evaluation processes, and develop paradigms to understand and direct all parts of the organizational system in the same direction to achieve quality objectives.

Another factor capable of affecting changes in product quality is market conditions, particularly market pricing. Generally, organizations sell and people want to acquire the benefits of products. Much as other aspects of the product, quality has benefits that potential buyers want, such as long product life, absence of faults and subsequent breakdown, reliability, and increase in value. However, for some types of products such as disposable goods (syringes or plastic cutlery) whose one-time benefits may be immediate, quality may take a backseat to such characteristics as hygiene, functionality, durability, or aesthetics. Quality may be emphasized because of the need to sell benefits. Prices can be raised if the product can offer added benefits, and generally, depending on what is important to buyers, price changes arising from improved product quality affect customer buying behavior. For instance, if price is not a major factor in the buyer’s analysis, a marginal increase in quality may prove more attractive.

Productivity studies tend to suggest that productivity increases improve quality, lower prices, and generally can affect society in significant ways. However, similar studies of the public sector show that there has been a lack of growth in the productivity in public services such as hospitals and public schools while, over time, the cost of providing public goods increases as a result of new technologies and better trained public service providers. Baumol’s cost disease is often used to describe this lack of growth in productivity and inflation in the cost of bureaucracy. Baumol (2003) argues that because many public administration activities are heavily labor-intensive and take place under relatively monopolistic market conditions, and because the demand for public goods is generally inelastic, there is little growth in productivity over time.

There is a widely held view that a high relative quality position (often incompatible with a low relative cost position) can be achieved through product differentiation. Product differentiation involves marketing or designing product that customers perceive as unique. Products may be differentiated along key features of the product or minor details, and at the market level, differentiation becomes the means by which the quality of goods is improved over time, mainly as a result of innovations such as introduction of new improved or better products. However, where goods presented in the market are ordered according to their objective quality so that one may be considered better than another, vertical differentiation occurs. This differentiation can be made along one definitive or decisive feature, along a few features each of which has a range of values, or across a large number of features each of which has only a presence or absence “lag.” It is possible with the last two to have a product that is better than another using one set of criteria but worse than the other using a different set of criteria. Common with supplied goods, vertical differentiation, which produces perceived differences in quality by different customers, may play a key role in customer buying behavior. Though advertising can influence or bias customer perceptions of these differentiating features, what makes the big difference in comparing widely different goods fulfilling the same needs is the nature of the need fulfilled, as often is the case with necessities or luxury goods.

This model of vertical product differentiation regards buyers in competitive market situations basically as price insensitive, for customers without their own opinion or means of judging quality will often rely on price to make their calculations of quality, so the quality-price relationship is often upwardly sloped. This model has been used to study the market structures that emerge from differentiation and to demonstrate that better production has a higher price and more expected benefits for consumers. However, a neoclassical model of product differentiation has been developed to explain the probable exploitation of market situations where customers exhibit bounded rationality because they lack knowledge and information-processing capability for market choices they make so that not all highly priced goods are of high quality (Piana 2003). This neoclassical model shows that the customer, a hyper-rational agent, maximizes utility by choosing an optimal collection of things and thus exhausts his or her budget.

In contrast, when products are differentiated by minor details or features that cannot be ordered, horizontal differentiation occurs. A model of horizontal product differentiation captures consumer behavior for various
versions of the market. For instance, ice cream flavors or a product with different colors or styles presents different versions of the same product. While consumers may have consistent preferences for one version or the other, it is common for a supplier of many versions of the same product to determine a unique price for all of them. Nevertheless, the rating of a product according to different measures of quality or taste depends on its physical and immaterial features. Manez and Waterson (2001) reviewed the implication of horizontal and vertical product differentiation on market structure under the assumption of single-product firms and also examined the major results of multiproduct firm models.

On the effects on product market and consumer behavior, Christou and Vettas (2003), in their study of advertising within a random-utility, nonlocalized competitive model of product differentiation, maintain that in a symmetric equilibrium, advertising is suboptimal when product differentiation is small and excessive otherwise. They believe that increasing the number of firms may increase or decrease the market price. They believe that in a quasi-concavity, profits may fall because firms may prefer price deviation as they target only those customers who are informed about their product.

Differentiation by quality protects a business from competitive rivalry, for it creates customer loyalty, lowers sensitivity to price, and protects the business from other competitive forces that reduce price-cost margins (Phillips, Chang, and Buzzell 1983). Competition may exist in the context of product rivalry where differentiation is achieved by both quality and brand or from some specific product characteristics or brand. Ford and General Motors both sell lines of automobiles having specific product features such as economy compacts, luxury cars, and so forth, and within these limits both companies provide similar offers, but then customers typically remain aligned to each depending on their valuation of quality or other perceived product benefits.

In a relatively free competitive market, vertical differentiation may permit businesses to increase profits by offering products that appeal to different types of customers, though cutthroat or head-on rivalry may result if customers perceive these products as good substitutes. Where, however, the market is open but monopolistic—what is often described as a “contestable market”—transient or opportunistic firms may not worry about quality as they may move in, exploit the gains, and leave before market conditions turn sour. Quality of goods and services enables an organization to achieve excellence and engage in profitable activities. Harold Greneer of ITT once remarked that quality was their most profitable product line, whereas IBM’s policy on quality has been one that seeks complete defect-free performance. In fact, IBM and ITT have in recent years invested millions of dollars on quality to reap immense benefits, which include cost reduction, increased profitability, and a reputation for excellence.

In spite of these apparent gains of quality, however, there appears to be inherent difficulties in measuring product/service quality. Quality is often perceived in relative terms and so presents the problem of determining how much good is “good,” what level of satisfying is “satisfactory,” or how high enough in the hierarchy of classes a product has to be before it is considered “classy.” These difficulties of assessment have given rise to many companies establishing acceptable quality levels (AQLs) for their products and services, a level determined by what each company considers appropriate.

QUANTIFICATION

Quantification is the act of giving a numerical value to a measurement of something, that is, to count the quanta of whatever one is measuring. Quantification produces a standardized form of measurement that allows statistical procedures and mathematical calculations. Quantitative research methods are based on a natural science, positivist model of hypothesis testing. In the social sciences these methods attempt to collect and analyze numerical data on social phenomena, seeking to understand the links between a relatively small number of attributes across a wide variety of cases. Thus, quantification is especially useful in describing and analyzing social phenomena on a larger scale.

THE RISE OF QUANTIFICATION

During the last centuries quantification has become immensely prevalent in the social sciences. Practices of quantification have been widely used in the West since the thirteenth century, and even before that. But only in the first part of the seventeenth century did the idea that social topics may be subjected to systematic quantitative analysis begin to acquire real dominance in Europe. These tendencies grew stronger during the nineteenth century, and by the first half of the twentieth century the “quantitative paradigm” had become extremely dominant in most of the social sciences, including economics, psychology, sociology, and political sciences.

There are a few prominent explanations for this growing use of quantitative measures in western society and in the social sciences in particular. First, the growing prominence and success of the natural sciences, especially physics, drove social scientists to imitate their use of quantitative measures in the hope of acquiring similar success and precision (see for example the 2002 book How Economics Became a Mathematical Science, by Roy Weintraub).

A second explanation emphasizes the rise of capitalism and the rational spirit in western societies, described by sociologist Max Weber in his 1905 book The Protestant Ethic and the Spirit of Capitalism. Weber describes a move toward a more rational, bureaucratic, and calculative life, and the increased tendency to quantify social entities and behaviors is well explained in light of these changes. Some scholars ascribe the proliferation of quantification mainly to the rise of the modern centralized state, in which public officials face the need to efficiently manage increasing populations and large-scale social institutions. Finally, in his 1995 book Trust in Numbers: The Pursuit of Objectivity in Science and Public Life, Theodore Porter suggests another interesting explanation. Porter argues that the tendency toward quantification in modern society is not so much a response to the success of the natural sciences, as it is an attempt of weak professional groups to pacify social and political pressures for greater accountability. In other words, according to Porter, the surge of quantification in the social sciences was driven mainly by the desire to create an appearance of professionalism and gain legitimacy for social research and public policies.

THE MERITS OF QUANTIFICATION

Quantification holds prominent advantages to scholars and policy makers. Its advocates believe that it increases precision and generalizability, while minimizing prejudice, favoritism, and nepotism in decision-making. According to this view, the decontextualized and value-free mathematical symbols used in statistical analyses assist in achieving objectivity, stability, and fair judgment as decisions become more businesslike. In this sense the quantification and standardization of the social life have liberating and emancipatory effects.

Quantification is also economical. Many feel that in today’s world, with the inevitable avalanche of numbers that arises from the growing state apparatuses and with the fast advancing information revolution, there is simply too much information to be efficiently handled with detailed qualitative descriptions. Trying to make complicated decisions without finding a way to reduce the amount of information to be considered may be overwhelming. Quantification, therefore, serves as a necessary tool for organizing and discarding information, making the flux of data more manageable. It recognizes that people have bounded cognitive skills and can only process limited amounts of information. Quantification saves time, helps in making sense and analyzing large datasets, and facilitates large-scale research, planning, managing, and decision-making. In light of these advantages, some scholars believe that every aspect of the social world can, and in fact should be quantified. Psychologist Edward Thorndike, for example, claimed at the beginning of the twentieth century that “Anything that exists exists in a certain quantity and can be measured’’ (Custer 1996).

THE SHORTCOMINGS OF QUANTIFICATION

But many disagree with this approach. First, critics of quantification claim that it sacrifices the substance and authenticity of the information. Transforming social experiences into standardized numbers leads to alienation and distances many groups from these experiences. It also allows decision makers to escape accountability, as numbers and statistics become refuge from personal responsibility. In that sense, quantification is actually a way of making decisions without seeming to decide, as decisions are left to the numbers. Quantification, according to its opponents, symbolizes the takeover of the market econ-
omy over social life, eliminating values of recreation and spontaneity. Another problem is that quantification facilitates the emergence of new categories such as “the nation” or “public opinion.” These terms are actually materializations of complex social actions and institutions, but in the process of quantification they turn into “things.” In the process of quantification, important information is lost for the sake of simplicity and calculability. But in areas such as environmental preservation, intimate relationships, identities, rights, and religion, these attempts often distort the nature of the category and fundamental qualities disappear. At the same time, the dominance of quantification also erases existing objects and relations, making some social phenomena, which cannot be quantified, practically invisible.

Finally, critics of quantification claim that it is often extended into areas in which it does not make statistical sense. This is especially true when measuring social entities, which are often flexible and subject to revision and change. For example social scientists often criticize the quantification of categories such as race and ethnicity, claiming that these are not real and stable entities, but rather fluctuating social definitions and classifications. This problem is exemplified in population censuses, in which some categories are invented and imposed on people by state officials, even when they do not coincide with personal identities and perceptions of self. In addition the interpretation of quantitative representations of social realities, such as race, fails to place these realities in the social context of the real world. This failure, in turn, may lead to misconceptions and erroneous judgments.

Despite these problems, quantification is clearly a process that cannot be avoided. It is an important and viable component of today’s social world, and there are few who would argue for returning to a prequantification world. Still, much more thought must be given to the problems of quantification and to its pitfalls. Researchers and policy makers must identify the places where it distorts the reality of social life and be much more cautious when applying it to social categories.

**BIBLIOGRAPHY**

**QUANTITY INDEX**

We begin our discussion of quantity indexes by setting up some basic notation: Let \( p^q = (p^q_1, \ldots, p^q_n) \) be a vector of prices for \( n \) goods in period 0. Let \( p^1 = (p^1_1, \ldots, p^1_n) \) be a vector of prices for the same \( n \) goods in period 1. Similarly, let \( q^0 = (q^0_1, \ldots, q^0_n) \) and \( q^1 = (q^1_1, \ldots, q^1_1) \) represent quantity vectors for the \( n \) goods in periods 0 and 1, respectively.

Total expenditure in the two periods is the sum (across all \( n \) goods) of the prices multiplied by the corresponding quantities: \( \sum_{i=1}^{n} p^0_i q^0_i \) and \( \sum_{i=1}^{n} p^1_i q^1_i \).

Thus, the ratio of total expenditures in the two periods equals \( Y^1/Y^0 \). If total expenditure is increasing from period 0 to period 1, then \( Y^1/Y^0 \) exceeds 1. If total expenditure is decreasing, then \( Y^1/Y^0 \) is less than 1. Total expenditure can increase from one period to another simply because prices are increasing. For example, suppose that the quantity vectors are identical in the two periods but the prices of all \( n \) goods increase from period 0 to period 1; then total expenditure will also increase.

Quantity indexes can be used to remove the effects of price changes in order to facilitate comparison of expenditures in different time periods. We will use the notation \( Q_{01} \) to denote a quantity index between periods 0 and 1. If the quantity index exceeds 1, then it means that expenditure is increasing from period 0 to period 1 after the effects of price changes have been removed. Similarly, if it is less than 1, then it means that expenditure is decreasing after the effects of price changes have been removed. In the context of national income accounting, quantity indexes can best be thought of as measuring changes in
real or inflation-adjusted expenditure; see “How Do I Use Chain-Type Indexes (or Chained Dollar) Measures of Economic Activity, Such as Real GDP?” under FAQs at http://www.bea.gov/index.htm.

A simple and easy-to-interpret way to remove the effects of price changes and, therefore, to calculate a quantity index would be to compare the cost of the quantity vectors in the two periods using a common set of prices. The Laspeyres quantity index, for example, uses the prices from period 0 and is defined as follows: \( Q_{01}^L = \sum_{i=1}^{n} \frac{p_{0i} q_{0i}}{p_{i0} q_{0i}} \).

If \( Q_{01}^L \) exceeds 1, then it means that the period 1 quantity vector costs more than the period 0 quantity vector in period 0 prices. Similarly, if \( Q_{01}^L \) is less than 1, then it means that the period 1 quantity vector costs less than the period 0 quantity vector in period 0 prices.

The Paasche quantity index is analogous to the Laspeyres quantity index, but with the period 1 prices replacing the period 0 prices. The resulting index is defined as follows: \( Q_{01}^P = \sum_{i=1}^{n} \frac{p_{i1} q_{0i}}{p_{i0} q_{0i}} \). If the quantity vectors are identical in the two periods, then both \( Q_{01}^L \) and \( Q_{01}^P \) will equal 1 even though \( Y^1/Y^0 \) may well differ from 1.

Later, we will develop the concept of superlative quantity indexes, which are preferable to these simple quantity indexes.

PRICE INDEXES, QUANTITY INDEXES, AND THE WEAK FACTOR REVERSAL TEST

Price and quantity indexes are closely related concepts. A price index, \( P_{01} \), is a function of the price and quantity vectors in periods 0 and 1, which measures the change in the prices of the \( n \) goods between the two periods. If it is greater than 1, it means that prices increased from period 0 to 1. If it is less than 1, it means that prices decreased.

A price index and a quantity index satisfy the weak factor reversal test if the following equation holds: \( P_{01} Q_{01} = Y^1/Y^0 \). Weak factor reversal can be used to formalize our interpretation of quantity indexes as removing the effects of price changes in order to facilitate comparison of total expenditure in two different time periods.

Assume, just for simplicity, that both total expenditure and prices are increasing between the two periods, so that \( Y^1/Y^0 > 1 \) and \( P_{01} > 1 \). If the percentage increase in prices, implied by the price index, is exactly the same as the percentage increase in total expenditure, then \( P_{01} = Y^1/Y^0 \) and, consequently, the quantity index will equal 1. If the percentage increase in prices exceeds the percentage increase in total expenditure, then \( P_{01} > Y^1/Y^0 \), implying that the quantity index will be less than 1. Conversely, if the percentage increase in total expenditure exceeds the percentage increase in prices, then \( Y^1/Y^0 > P_{01} \), implying that the quantity index will exceed 1.

COST OF LIVING, STANDARD OF LIVING, AND SUPERLATIVE INDEXES

Tripplett discusses the connection between price and quantity indexes for a set of consumer goods and services and the concept of a cost-of-living index:

A consumption price index should measure the change in the cost of maintaining a fixed, or constant, standard of living. If the price index holds the standard of living constant, then any increase in per capita consumption expenditures that exceeds the increase in the price index can be interpreted as an increase in the standard of living.… Thus, from the standard-of-living orientation, the price index measures the changing cost of a constant standard of living, and the quantity index measures increases or decreases in the standard of living. (1992, p. 49)

Dievert (1976) provided a strong rationale for preferring certain price and quantity indexes, which he termed superlative. Without focusing on technicalities, a price index is superlative essentially if it provides a good approximation to the changing cost of a constant standard of living using only the observed price and quantity data. A more extensive discussion of the concept of a cost-of-living index and its connection to superlative price indexes can be found in the entry Price Indices.

A pair of price and quantity indexes is said to be a superlative pair if one of them is a superlative index and the other is defined implicitly by the weak factor reversal test. Thus, for our purposes, it will suffice to interpret a superlative quantity index as one that satisfies the weak factor reversal test in conjunction with a superlative price index (we note, however, that superlative quantity indexes can be defined independently of superlative price indexes without reference to weak factor reversal; see Dievert 1976). In practical terms, following Tripplett, this means that superlative quantity indexes can be interpreted as measuring increases or decreases in the standard of living. For an authoritative survey of index number theory, including superlative indexes, see Dievert (1981).

The Laspeyres and Paasche quantity indexes, discussed previously, are not superlative. There are, however, many price and quantity indexes that are known to be
superlative. Among these, indexes based on Fisher’s ideal formula have been widely used. Fisher’s ideal price index is defined as:

\[ P_{01}^{FI} = \sqrt[\sum_i \sum_j p_i^0 q_j^0 / \sum_i \sum_j p_i^1 q_j^0}. \]

The corresponding quantity index is defined as:

\[ Q_{01}^{FI} = \sqrt[\sum_i \sum_j p_i^1 q_j^0 / \sum_i \sum_j p_i^0 q_j^0]. \]

Fisher’s ideal quantity and price indexes are both superlative and, in view of the weak factor reversal test, together they constitute a superlative pair.

In the same paper, Diewert also proves that the Torrnqvist-Theil quantity index is superlative. The Torrnqvist-Theil quantity index, \( Q_{01}^{TT} \), is defined as:

\[ Q_{01}^{TT} = \prod_{i=1}^n \left( \frac{q_i^0}{q_i^1} \right)^{w_i^0 / \sum_i w_i^0 + w_i^1}, \]

where \( w_i^0 = p_i^0 q_i^0 / Y^0 \) and \( w_i^1 = p_i^1 q_i^1 / Y^1 \) are the expenditure shares for good \( i \) for periods 0 and 1 respectively. A corresponding implicit price index can be obtained for this index using the weak factor reversal test.

CHAIN-WEIGHTING

Suppose that we have price and quantity data for many periods denoted by \( p_i \) and \( q_i \), where \( t = 0, 1, \ldots, T \) (for example, suppose we have annual data for twenty years). This allows us to compute quantity indexes from each period to the successive one, \( Q_{t-1,t} \) for all \( t \). We can produce a time series covering more than two periods using the concept of chain-weighting. A chain-weighted time series can be constructed as follows: The value of the series, \( I_t \), for any period \( t \) is the previous value of the series, \( I_{t-1} \), multiplied by the corresponding quantity index for the two periods, so that \( I_t = I_{t-1} Q_{t-1,t} \) for all \( t \) (see Bureau of Economic Analysis 2006, Appendix 1). Thus, the growth rate of a chain-weighted index between adjacent periods is \( (I_t - I_{t-1}) / I_{t-1} = Q_{t-1,t} - 1 \).

FROM THEORY TO PRACTICE

National statistical agencies, such as the Bureau of Economic Analysis (BEA), use chain-type quantity indexes to estimate changes in real or inflation-adjusted gross domestic product (GDP) and its components, which can be used when making comparisons over time. BEA (2006) discusses the background and history of the national income and product accounts (NIPAs) for the United States.

As noted by BEA (2006, p. 2), “in 1996, BEA introduced several major improvements to the NIPAs. BEA began estimating the changes in real GDP and its components by chaining together year-by-year quantity changes that were calculated using the Fisher index formula, rather than estimating real GDP on the basis of prices of a single, arbitrary base year.” The previous method tended to cause an underestimation of real GDP growth for periods prior to the reference year and an overstatement of real GDP growth for periods after the reference year, which is called substitution bias in real GDP growth. These and other problems are eliminated by the use of Fisher’s ideal formula (see BEA 2006, p. 15).

Quantity indexes are useful in other contexts as well. For example, the Federal Reserve Bank of Saint Louis and the Bank of England both produce chain-weighted monetary aggregates based on the Torrnqvist-Theil quantity index formula; see Anderson, Jones, and Nesmith (1997) and Hancock (2005), respectively. The Federal Reserve Bank of Saint Louis refers to its superlative monetary aggregates as monetary services indexes, while the Bank of England refers to its as Divisia money. Monetary aggregates include many different types of components—for example, currency, checking accounts, savings deposits, money market mutual funds, time deposits, and the like—which vary in terms of their usefulness for making transactions. As argued by Hancock (2005), Divisia money is a gauge of the money supply that gives the greatest weight to the components of the aggregate that are most used in transactions.

EMPIRICAL ILLUSTRATION

As noted above, the BEA estimates changes in real GDP and its components for the United States by employing chain-type quantity indexes based on Fisher’s ideal formula. In this section, we show how real GDP growth is related to the U.S. business cycle to illustrate the use of quantity indexes.

We obtained the chain-type quantity index for real GDP from BEA and calculated its annualized quarterly growth rate from 1947 to 2006. As identified by the National Bureau of Economic Research (NBER) (see http://www.nber.org/cycles.html) there were ten recessions over the period from 1947 to 2006. These recessions are strongly associated with negative real GDP growth, whereas real GDP growth is usually, although not always, positive when the United States is not in a recession. Annualized quarterly real GDP growth averaged 3.4 percent over the entire period from 1947 to 2006. By comparison, averaging over just the recessionary quarters (peak to trough inclusive) yields average annualized quarterly real GDP growth of –1.2 percent.
As noted by the Business Cycle Dating Committee of the NBER (2001), the financial press often defines a recession as two consecutive quarters of decline in real GDP. While this is true of most of the recessions identified by NBER, it is not true of all of them.

QUANTITY THEORY OF MONEY

The quantity theory of money (QTM) refers to the proposition that changes in the quantity of money lead to, other factors remaining constant, approximately equal changes in the price level. Usually, the QTM is written as $MV = PY$, where $M$ is the supply of money; $V$ is the velocity of the circulation of money, that is, the average number of transactions that a unit of money performs within a specified interval of time; $P$ is the price level; and $Y$ is the final output. The quantity theory is derived from an accounting identity according to which the total expenditures in the economy ($MV$) are identical to total receipts from the sale of final goods and services ($PY$). This identity is transformed into a behavioral relation once $V$ and $Y$ are assumed as given or known variables.

The QTM dates back to sixteenth-century Europe where it was developed as a response to the influx of precious metals from the New World, and in this sense it is one of the oldest theories in economics. Nevertheless, only in the writings of the late mercantilists does one start to find theoretical statements that justify the connection between $M$ and $P$. David Hume (1711–1776) argued that assuming a case of equilibrium, an expansion in $M$ (for example, through the discovery of new gold mines) would make a group of entrepreneurs richer, and their rising demand would increase the prices of products, thereby increasing the income of another group of entrepreneurs whose demand would increase the price level even further, and so forth. These chain effects at some point die out, and their end result would be the restoration of equilibrium, albeit at a higher price level. Hume and the mercantilists did not back up their claims by developing a theory of value and distribution; for them, the QTM was explained either mechanically or through the operation of competition.

In contrast to Hume, for classical economists the QTM became a constituent component of their theory of value and distribution. Invoking Say’s Law of markets, according to which output can be taken as given, and assuming that $V$ is also given for it is determined by the customs of payments and the institutional arrangements of society, it then follows that proportional changes in $M$ will be reflected in $P$ and vice versa. David Ricardo (1772–1823) in particular reversed the usual causal relationship of the QTM arguing that changes in $P$ lead to changes in $M$ and not the other way around. The idea is that the value of gold (money) is a kind of a numéraire for all other prices, which means that if the quantity of money becomes more abundant because of the rise in productivity of gold mines (because of the discovery of new gold mines or technological change), it follows that the price of gold falls and, therefore, the prices of all other commodities rise. Alternatively, if total output increases, the subsequent scarcity of money raises its price above the normal level, and the excess profits in gold production lead to the expansion of supply, thereby reducing the price of gold, which returns to its normal level, and equilibrium is restored at a higher price level. Thus, the normal price of gold is what actually determines the quantity of money in circulation. Consequently, the difference between Ricardo and the mercantilists is that the arrow of causality runs from $P$ to $M$ and, therefore, the quantity of
money is endogenously determined—that is, it is determined within the economic system.

The quantity theory continued in the writings of the neoclassical economists, with the issue of exogeneity predominant in the work of Irving Fisher (1867–1947). The so-called Fisher’s equation of exchange (1911) can be stated as follows: \( MV + M'V' = PT \), where \( M \) is currency and \( M' \) is demand deposits; \( V \) and \( V' \) are the respective velocities; and \( T \) stands for total volume of transactions and not only of final goods. Another interesting development is that associated with Knut Wickell (1851–1926), who stressed the endogenous character of the money supply, which is responsible for the variations in the price level. The advent of Keynesian economics in the 1930s rendered the QTM of minor importance, and it was used only for the determination of nominal magnitudes of real variables.

According to Keynesian analysis the quantity of money could not affect the real economy in any direct way but only indirectly through variations in the interest rate. In contrast, a characteristically different view has been expressed by economists at the University of Chicago. More specifically, Milton Friedman (1912–2006) claimed that money matters and is responsible for almost every economic phenomenon. In fact, Friedman argued that the major economic episodes in U.S. economic history—from the Great Depression of the 1930s to the inflation of 1970s—could be explained through variations in money supply. During the mid-to-late 1960s the appearance of stagflation and the rejection of the usual Phillips curve were registered as a blow against Keynesian economics and facilitated the acceptance of monetarism and its establishment as a school of economic thought with significant appeal. Friedman not only showed the inadequacy of Keynesian economics to deal with stagflation but he also proposed an explanation based on the concept of the natural rate of unemployment—that an expansionary economic policy affects the economy only in the short run, while in the long run the economy returns to the natural rate of unemployment but this time with higher inflation.

Friedman and the monetarists express the QTM in terms of growth rates, which means that they consider as a given, in the beginning at least, the velocity of money circulation, and thus that the growth rate of money supply influences the growth rate of nominal output identified with the nominal gross domestic product (GDP), that is, the product of the real GDP times the general price level. Later, when Friedman introduced the notion of natural unemployment, it could be argued that in the long run, at least, the real GDP is equal to full employment GDP, which corresponds to the level of natural unemployment, and thus the growth rate of GDP is known in the long run. Consequently, in the long run the growth rate of the money supply—to the extent that it exceeds the growth rate of the real GDP—increases the growth rate of the price level, that is, the rate of inflation.

According to Keynesians the velocity of money is characterized by high volatility; consequently, changes in the supply of money can be absorbed by changes in the velocity of money with negligible effects either on output or on the price level. These arguments emphasize that the velocity of money depends on consumer and business spending impulses, which cannot be constant. A similar view is shared by economists of the neoclassical synthesis, especially in the case in which the economy is in the liquidity trap, whereby, regardless of the changes in the supply of money, the real economy is not affected at all. Changes in the supply of money are absorbed by corresponding changes in the velocity of money. Furthermore, the effect of money supply on prices may work indirectly through variations in interest rates, which in turn induce effects on aggregate demand.

The empirical evidence with respect to the effects of the money supply on the price level so far has been mixed and depends on the definitions of the money supply (narrow or broad) and the time period. As a consequence, the velocity of the narrow money supply, \( V_1 = \frac{GDP}{M1} \), for the U.S. economy has displayed a rising trend during the period 1920–1929, a falling trend during the period 1929–1946, an upward trend in the period 1947–1981, erratic behavior along a falling trend during the period 1981–1991, and an upward trend since then. The erratic behavior of the 1980s has been attributed to the deregulation of the banking industry and the appearance of new checkable accounts. Clearly, the overall movement of \( V_1 \) is associated with the long-run upward or downward stage of the economy. The results with respect to the U.S. data prove somewhat better for the monetarist argument with regard to the velocity \( V_2 = GDP/M2 \). A closer look at \( V_1 \) or \( V_2 \) in monthly or quarterly data reveals substantial fluctuations in the short run. The variability of the velocity of circulation has been attributed, among other things, to the frequency of payments, the efficiency of the banking system, the interest rate, and the expected inflation rate. From the above it follows that the causal relationship between money supply and price level—that is, the issue of exogeneity versus endogeneity—is not settled yet and, therefore, continues to attract the attention of economists. There is no doubt that the discussion will continue in the future as economists try to understand better the interrelations of monetary and real economic variables.

QUEBECOIS MOVEMENT
The Quebecois movement of the late twentieth century was the product of long-standing strained relations between the francophone (or French Canadian) and anglophone (or English Canadian) populations of Canada. From these deep historical roots, the Quebecois movement grew into an important force shaping Canada’s current social, political, and economic conditions. Although the movement has at times sought sovereignty for Quebec, recent developments suggest that such an outcome is highly unlikely.

Tensions between anglo- and francophone settlers in colonial North America mirrored those among the imperial powers of the period but took on their own character. For example, French settlers interacted more easily with Native Americans than did the British, and this relationship both affected and reflected the balance of power each European group perceived in eighteenth-century North America. In fact, the war known variously as the French and Indian War (in the United States), the Seven Years War (in Europe and English Canada), or the War of Conquest (in French Canada) had been raging in North America for two years before European powers actually declared war on one another in 1756. One decisive element of that war was the rapid and thorough defeat of French forces by the English at the Plains of Abraham, upstream from Quebec City, on September 13, 1759. That defeat led to the withdrawal of French imperial governor from Canada and set the stage for British domination. While the British did make some conciliatory gestures toward French Canadians, notably in the 1774 Quebec Act, cultural and economic competition and hostility between English and French Canadians continued unabated. In a report to the British government, Lord Durham, the governor general of British North America from 1837 to 1838, famously described the two groups as “two nations warring in the bosom of a single state.” As a remedy, he suggested aggressive assimilation of French Canadians into the British system.

French Canadians balked at being anglicized and resisted repressive moves by English Canadians, such as abolition of bilingual and Catholic schools in New Brunswick and Manitoba, respectively, in the 1870s. By this time, Canada was independent from Britain, and French Canadians soon found themselves united in opposition to Ottawa’s alignment with British military policy. The 1899 Boer War was particularly odious to French Canadians, who regarded it as simple British imperialism, a phenomenon they themselves had experienced as oppressive. In this political climate, French Canadians continued to experience everyday humiliations and bigotry at the hands of English Canadians, who generally regarded them as inferiors.

TWENTIETH-CENTURY DEVELOPMENTS
At the turn of the twentieth century, Prime Minister Wilfred Laurier emphasized that the Canadian confederation had been founded on the concept of “two nations.” The obvious domination of one nation by the other was antithetical to the logic of confederation. When the Great Depression struck, French Canadians were much harder hit than their English counterparts, giving painful evidence of the terrible economic disadvantage under which the Quebecois labored. Crises over conscription in both world wars showed the depth of French Canadian distrust of Canadian military policy. For example, a 1942 plebiscite showed that nearly 80 percent of English Canadians supported entering World War II, while the same margin of French Canadians opposed doing so.

Arguably, the contemporary Quebecois movement began in the 1960s with the Quiet Revolution. This was a trend in French Canadian politics toward more aggressive political demands for special status within Canada and a new emphasis on the Quebec provincial government as the instrument of change. The Liberal provincial government of Jean Lesage began the process in 1960 under the slogan “Maîtres chez nous” (“Masters of our own house”), demanding that Ottawa recognize Quebec as having a “special status” that afforded the province economic and social powers unique in Canada. At the national level, the
Liberal Party under Prime Minister Lester Pearson responded to these developments in part by recruiting more French Canadians, including Pierre Elliott Trudeau, who would later serve as prime minister and be an important figure in Anglo-French relations. Trudeau entered federal politics in 1965, believing that neither Quebec separatism nor a special status for the Quebecois was in the best interest of Canada. He swiftly rose through the ranks of power, succeeded Pearson as leader of the Liberal Party, and in 1968 became prime minister. In the same year, several provincial parties advocating varying degrees of Quebecois separation from the rest of Canada joined forces to create the Parti Québécois (PQ, or Péquistes), under the forceful and charismatic leadership of René Lévesque. The Péquistes advocated a plan of sovereignity-association, in which Quebec would be politically independent from, but economically linked to, the rest of Canada.

Quebec's 1970 provincial elections were a watershed, passionately debated and anxiously watched throughout Canada. If Lévesque and the Péquistes gained control of the provincial legislature, separation seemed sure to follow. In fact, the provincial Liberals, led by Robert Bourassa, won handily, and the Péquistes took only 7 of 108 seats. Sparked by this loss, the terrorist Front de Libération du Québec (FLQ) kidnapped James Cross, Britain's trade commissioner in Montreal, and Pierre Laporte, a cabinet minister of the Quebec government. In exchange for the hostages, the FLQ demanded funds, the release of FLQ-sympathizing prisoners (whom Trudeau referred to publicly as "bandits"), and promulgation of their manifesto. This became known as the October Crisis. Trudeau's government responded by passing the War Measures Act, which gave police and government extra leeway to use force domestically and led to the unusual circumstance of tanks and armed soldiers in Canadian streets. When asked by a reporter how far he would go to defend his position, Trudeau famously responded, "Just watch me." While the majority of Canadians did not sympathize with the FLQ, the War Measures Act was highly controversial. The crisis ended when Cross was freed, Laporte was killed, some kidnappers were given safe passage to Cuba, and others were captured. Nonetheless, a significant minority of French Canadians sympathized with at least some of the FLQ's position, and the federal government still had to address Quebec's concerns.

In 1974 and 1976, Quebec's provincial legislature passed two laws—Bill 22 and Bill 101 (the latter also known as the Charter of the French Language)—declaring French the province's official language, mandating French-language schools for immigrants, and requiring the use of French in the workplace. These laws were generally well received by francophone residents of Quebec but were highly controversial among English-speaking and other Quebeckers and in Canada as a whole.

Trudeau's Liberal government was reelected in 1980, and the prime minister set a high priority on patriating the Canadian Constitution. Canada had been created in 1867 by the British North America Act, an act of the British Parliament. Arguably, then, Canada existed only with another state's permission. A true sovereign declares its own sovereignty, and Trudeau believed Canadians' own sense of nationality hinged on this distinction. For these and other reasons, Trudeau's government wished to change Canada's founding document from an act of the British Parliament to an act of the Canadian Parliament. The process of shifting from the British North America Act to a truly Canadian document was known as patriation of the Constitution.

Trudeau's government had reason to hope Quebec would not be a stumbling block in this process. Also in 1980, the Parti Québécois introduced a provincial referendum asking for a mandate to negotiate a new relationship between Quebec and the rest of Canada; the referendum failed. The Liberals' optimism must have vanished quickly, however, since the following year the Parti Québécois was reelected with substantially increased support. The referendum was not a clear indicator of the complex situation in Quebec. Ultimately, the federal government formulated a new Constitution (in the Constitution Act of 1982), with a Charter of Rights and Freedoms to address some of the human-rights concerns of, among others, French Canadians. The Constitution Act, which represented compromise by the national government as well as the provinces, was accepted by Ottawa and every provincial government except Quebec's.

In 1984, the Liberals lost control of Parliament to the Conservatives. Brian Mulroney, the new prime minister, made a priority of resolving constitutional tensions with Quebec and met with Robert Bourassa at Meech Lake, Ontario, in 1987. As a result of the Meech Lake conference, the national government agreed to propose constitutional changes recognizing Quebec as a "distinct society" within Canada; stating that the coexistence of French and English speakers is fundamental to Canadian society; and affording Quebec a role in choosing supreme court justices, making immigration policy, and vetoing constitutional amendments. Bourassa was satisfied with the Meech Lake Accord, but the agreement rankled some nonfrancophone Canadians by seemingly giving the Quebecois a privileged position ahead of other groups, such as aboriginals and women. Although Ottawa and eight provincial governments approved of the accord, holdouts in Manitoba and Newfoundland succeeded in killing the agreement in 1990.
The Quebec government announced another referendum on sovereignty for 1992. In hope of preempting separation, the national government proposed a new conference, this time at Charlottetown, Prince Edward Island, to work on constitutional issues. Ottawa hoped to reconcile Quebec’s demands with those of aboriginal groups, social groups protected under the charter, and various economic demands of the provinces. This proved a monumental task, and the result pleased few parties. Ultimately, only four provinces approved the Charlottetown Accord, while six (including Quebec) rejected it.

In 1995, the Quebec government held its second referendum (the first being in 1980) on separation. The margin of victory was almost the smallest imaginable: 49.4 percent favoring sovereignty for Quebec, 50.6 percent opposing. The run-up to this vote spurred passionate discussion across Canada about what it means to be Canadian, and the reporting of election returns was both politically and emotionally fraught. In 1998, charismatic politician Lucien Bouchard of the Bloc Québécois (a political party with candidates at the national level, whereas the Parti Québécois stands candidates only at the provincial level) began calling for the people of Quebec to consider asking Ottawa for a new deal. The national government responded by requesting an opinion from the Supreme Court of Canada on the domestic and international legality of Quebec’s secession. In 2000, the Court ruled that Quebec could not unilaterally secede from Canada and that the conditions facing Quebec did not constitute persecution under international law. However, a “clear expression of a clear majority of Quebeckers” for sovereignty would require a serious response from the national government or else would call into question the democratic legitimacy of the Canadian government. Since the Court’s ruling, separation seems unlikely, although the Bloc and Parti Québécois remain important voices in Canadian politics.

Queer Studies

FORMED OUT OF SCHOLARLY CONFERENCES IN THE 1980s, Queer studies started as an elite academic movement of primarily humanities scholars who had taken a lead in developing lesbian and gay social constructionist studies in the 1980s (Fuss 1991). Social science scholars were largely absent from its beginning intellectual formations (see, for example, Fuss 1991; Abelove et al. 1993; Warner 1993).

Correcting for this absence, two important edited volumes stand out in foregrounding a queer perspective for the social sciences and, conversely, a more social standpoint for queer studies. The first is Queer Theory/Sociology (1996). In his introduction to the volume, Seidman argues that queer theory wants to shift the study of sexuality “from explaining the modern homosexual to questions of the operation of the hetero/homosexual binary, from an exclusive preoccupation with homosexuality to a focus on heterosexuality as a social and political organizing principle, and from a politics of minority interest to a politics of knowledge and difference” (1996, p. 9). While this volume importantly situates the development of sexuality studies within earlier British sociological work on homosexuality (e.g., McIntosh 1996; Plummer 1996; Weeks 1996), its intersectional queer/sociology focus provides empirical studies that illustrate the postmodern critique of identity as multiple, exclusionary, and performative.

As Steven Epstein (1996) and Arlene Stein and Ken Plummer (1996) noted, earlier sociological work on sexuality as socially constructed was problematically absent from the new onslaught of queer studies scholarship. Instead, queer studies theoretically centered Michel Foucault’s work (1978) and those of his followers, particularly Judith Butler (1990, 1993) and Eve Sedgwick (1990, 1993), making them the triumvirate benchmarks in the field. Setting the bar for analytical virtuosity, Sedgwick’s statement in Epistemology of the Closet (1990) triumphs the need to make sexuality and the hetero/homo binary part of every analytical study of modern Western culture. Later historical studies, such as George Chauncy’s (1994), date the rise of the closet to the 1930s and its intensification during the cold war, when state-sanctioned homosexual discrimination became patterned and systematic. Similarly, Seidman’s (2002) sociological genealogy of the closet’s rise and fall over the last half-century empirically concretizes the closet’s social shifts and
changes. Interestingly, the theoretical acumen of Butler's work, and its ironically enabling programmatic framework, on identities as performative, specifically in their striving to perform idealized versions of heteronormative and gender-normative forms, serves as a theoretical cradle for empirical studies on intersectional identities of sexuality, gender, race, and class (e.g., Stein 1997; Esterberg 1997; Bettie 2002; Salzinger 2003).

Social Perspectives in Lesbian and Gay Studies (1998), edited by Peter Nardi and Beth Schneider, is the other key reader in sociology that highlights a queer perspective as the latest word in conceptualizing sexualities. However, in his afterword to the volume, Plummer (1998) notes the limitations of what he calls the “Foucauldian deluge” on sociology and is critical of its overemphasis on discourses and texts to the detriment of empirical social research more broadly (see Green [2002] for a similar critique of queer theory).

Contradictorily, since the mid-1990s, queer studies and the sociology of sexualities have converged in their analytical focuses while continuing to remain apart in their conversations and debates (see, for example, David Eng et al. [2005] on queer studies in a double issue of the journal Social Text and Joshua Gamson and Dawne Moon [2004] in their review of queer studies and its status in the sociology of sexualities). The fields converge, however, in their Foucauldian conceptualization of power as disciplinary, exclusionary, and normalizing, as well as in their studying of identities, institutions, and relations of state, nation, and globe. Still, queer studies' latest voices remain scholars from primarily the humanities (see Eng et al. 2005). And the sociology of sexualities, although drawing strongly on queer studies, remains distant from its emphasis on discourse/text, its poststructural antinormative theoretical presuppositions that typically eschew identity altogether, and its use of antihumanist language to problematize identity categories and the written text itself (see Butler's [1995] and Fraser's [1995] exchange as exemplars of these issues).

These contradictions notwithstanding, queer studies and the sociology of sexualities come together in their analysis of identities, from their gender and sexual interaction to the problematizing of heterosexual identities to the analyzing of the multiple ways race, class, and gender, in addition to sexuality, interact, and finally to the very limit of identity itself. Additionally, the two fields have made the relationships between processes of sexualities and nationalism, colonialism, and globalization key trends as well. This entry will briefly review some of these convergences in detail.

In rethinking sexual and gender-identity formations, Judith Halberstam's (1998) and R. W. Connell’s (1987, 1995) works on female masculinity and hegemonic masculinity, respectively, help queer studies scholars to rethink conceptions of dominance and resistance. Female masculinity, for Halberstam, extends the concept of masculinity beyond men to include women, and views masculinity as a general form of gender expression and practice that lesbians, butch lesbians, butch women, as well as nonlesbian females, draw on to project authority, strength, and aggression in social life. Conceptualizing the intersection of compulsory heterosexuality and male dominance, Connell’s concept of hegemonic masculinity links heterosexual male practices of homophobia and sexism to the subordination of femininities and dominated masculinities.

Building on the work of Monique Wittig (1992), Adrienne Rich (1980), and Connell, queer studies continues to make compulsory heterosexuality and heterosexual identities problematic and in need of social explanation. From Jonathan Katz’s (1996) historical overview of the development of heterosexuality as an ideology and an identity over the nineteenth and twentieth centuries to Chyrs Ingraham’s (1996, 1999) concept of the heterosexual imaginary and its ideological role in white weddings or Elizabeth Freeman’s (2002) work on marriage, weddings, and heterosexualities, queer studies continues to attempt to undo compulsory heterosexuality’s hegemony.

As Gamson and Moon note, “Long before queer theory began speaking of ‘multiple identities,’ black feminists had articulated an intersectional analysis of oppression that recognized race, gender, class, and sexual oppression as interlocking systems” (2004, p. 52). Since the early 1980s, scholarship on intersectionality has proliferated in the field. Stein's (1997) study of generational differences between two cohorts of lesbians makes age, history, and social conditions central aspects in explaining differences among lesbians who came out in the 1970s in comparison to the 1990s. Analyzing the racial, gender, class, and sexual intersections of mostly queer people of color on talk shows, Gamson’s (1998) study demonstrates struggles over queer visibility and media representation. Furthermore, from humanities scholars like Tavia Nyong’o (2005), whose work illustrates the exclusions but also social necessities of intersectional identities like the pejorative punk, and intersectional sociologists like Roderick Ferguson (2004), who approaches the social through combining social theory, sociology, and literature, to Chet Meeks (2001), who theorizes the limits of sexual identity and liberation and develops a politics of antinormalization to underscore sexual differences beyond identity, scholarship on intersectionality demonstrates the hybrid importance of this research in queer studies.

The last key trend in queer studies is scholarship on nationalism, colonialism, and globalization and its relation to sexual practices. Important work by Joyti Puri...
(1999) shows the continuities and discontinuities in transnational discourses of menstruation, marriage, pornography, and homosexuality for Indian women today. Focusing on the relationship between sexual and colonial practices, Ann Laura Stoler's (2002) study of Dutch colonial rule in nineteenth- and twentieth-century Indonesia demonstrates the way colonial practices organized sexuality, intimacy, and family in shaping the relationships between Dutch men and the native Indonesian women they had sex with and made “concubines.” Finally, Chandan Reddy (2005) details the uses and abuses of gay Pakistani asylum seekers in the U.S. policy of “family reunification,” which simultaneously makes asylees part of a class of low-wage workers in the United States.

In short, queer studies' focus on identity and its multifarious constructions, as well as its engagement with scholarship on nationalism, colonialism, and globalization, illustrates the field's intellectual efflorescence, contemporary relevance, and vanguardism.

QUESNAY, FRANÇOIS
1694–1774

François Quesnay was born in the village of Méret, Ile de France, into a family of merchants and small landowners. As a child he received no formal training, but he learned to read and write from a gardener. Largely self-taught, in 1711 he began to study medicine and surgery in Paris. In 1717 he married; he had three children. He first earned a living as a surgeon and contributed several essays to the controversy between surgeons and physicians in France in the 1740s. In 1734 he assumed the position of physician of the Duke of Villeroy and in 1749 of Madame the Pompadour, Louis XV’s favorite, in Versailles. In 1752 he saved the dauphin from smallpox, which won him the king’s favor, a noble title, and a significant amount of money. At the beginning of the 1750s he was elected a member of the Académie des Sciences, Paris, and the Royal Society, London. During this period Quesnay stopped publishing medical works and turned to economics. The years 1756 and 1757 saw the publication of his entries in the Encyclopédie on Fermiers (farmers) and Grains (corn). Three further entries devoted to Hommes (people), Impôts (taxes), and Intérêt de l’argent (money rate of interest) could not be published in the Encyclopédie after an attempt to assassinate the king, which was grist for the mill of the enemies of the encyclopédistes (d’Alembert, Diderot, and others) and brought the project to a standstill. The first two articles were published only at the beginning of the twentieth century, the third in 1766.

Of particular importance to Quesnay’s works in economics and their impact on the contemporary political debates first in France and then beyond was his encounter with the Marquis de Mirabeau in 1757. Mirabeau became a close follower of Quesnay and untiringly spread the gospel of the new physiocratic school. In 1758 Quesnay composed the first edition of the Tableau économique, which contained the first schematic account of the intertwined processes of production, distribution, and disposition of the riches of an entire nation. Mirabeau compared the importance of the Tableau to that of the discovery of fire and the wheel; Marx called it the “most brilliant idea” of political economy up until then and the physiocrats “the true fathers of modern political economy” (Marx 1963, p. 44). Two further editions of the Tableau followed in 1759. In 1763 Mirabeau published the Philosophie rurale in three volumes, a work that was heavily influenced (and partly even written) by Quesnay. In the same year the physiocrats began to engage in economic policy debates. Their articles appeared first in the Journal de l’agriculture and then in Éphémérides du citoyen, the “sect’s” main outlet. Quesnay contributed several essays on themes such as the natural law doctrine, the so-called sterility of industry, and, in 1766, a simplified version of the Tableau in an article titled “Analyse de la formule arithmétique du Tableau économique.” The school’s influence in France peaked in the late 1760s and then steadily declined. Quesnay died in December 1774 near Versailles.

Quesnay conceived the process of production as a circular flow, with the rent of land being traced back to the existence of surplus product (produit net) left over after all means of production have been used up and all means of
subsistence in support of the laboring population have been deducted from annual gross outputs. With a social division of labor, the products have to be exchanged for one another in interdependent markets. In order for the process to be able to continue unhindered, prices must cover physical real costs of production, consisting of means of production and subsistence, plus, in agriculture, the rent of land. A major concern of Quesnay was with the system’s potential for growth. This depended on whether the surplus was consumed productively or unproductively and whether new methods of production could be developed and introduced, which by increasing productivity increased the social surplus.

Quesnay’s works had a major influence on the development of central concepts and analytical tools in economics. After him the idea of ubiquitous economic interdependence never left the realm of economics again. Marx’s analysis of simple and extended reproduction in volume 2 of Capital drew on the Tableau (see Marx 1974, and Gehrke and Kurz 1995), as did Wassily Leontief’s (1941) input-output analysis. Piero Sraffa’s (1960) reformulation of the classical approach to the theory of value and distribution was inspired by the physiocrats’ multisector analysis. Also inspiring Sraffa was the physiocrats’ concern with the implications for the theory of value and distribution of the specific conditions of the transformation of matter and energy into new forms of matter and energy in given sociotechnical conditions. Quesnay’s concept of production as a circular flow is in marked contrast with the view entertained by some marginalist economists such as Eugen von Böhm-Bawerk of production as a one-way avenue of finite duration leading from the services of original factors of production to final output. The concept of a closed system, as we encounter it in Quesnay, is employed in fields of economics that take into account the laws of thermodynamics, such as environmental economics.

**QUOTA SYSTEM, FARM**

Farm commodity quotas are defined as government-administered area or quantity allotments restricting what a farmer can produce or market. Such supply controls in the United States initially rested on several presumptions, some or all of which are no longer valid. One was that farmers reacting to market forces were incapable of adjusting their resources and output in a timely manner to maintain their income at a socially acceptable level in response to shocks from weather, foreign markets, and rapid productivity advance. That presumption in turn implied that, in the absence of supply control, farmers were predestined to chronically produce too much and hence to experience perennially low farm prices, incomes, and rates of return on resources.

Another presumption was that the demand for farm commodities was inelastic. That is, a reduction in market quantity would reduce quantity proportionately less than it would raise commodity price, thereby raising commodity receipts and farm income.

Supply controls in the form of quotas or allotments can be voluntary or mandatory, on resources or commodities, whole farm or part farm, on crop area or output, and short term or long term. Under the Agricultural Adjustment Act of 1933, the grandfather of farm commodity programs, government rewarded farmers who voluntarily controlled how much of major crops they planted with commodity price supports or direct payments.
The Agricultural Adjustment Act of 1938 introduced mandatory supply control. The term mandatory, though widely used, was nonetheless misleading because area quotas became binding on all producers of the commodity only if a two-thirds majority supported quotas in a national referendum. Due to generous price supports attending these quotas, farmers widely accepted mandatory controls. However, controls were largely ineffective in boosting total farm income because the area reduced for basic farm program crops was offset by area and production expansion for other crops. Slippage also was large because crop price supports encouraged additional application of fertilizers, irrigation water, and other inputs so that higher yields offset area cuts. Despite ineffective supply control, production was not excessive because of droughts in 1934 and 1936, and demand expansion during World War II.

Generous commodity support prices introduced in the 1940s were continued after the war, generating surpluses in the absence of supply control. Consequently, the government in 1954 introduced a conservation reserve program (CRP) to convert cropland, even whole farms, to long-term soil conserving uses. By 1960, 29 million acres were under 10-year contracts.

Farmers idled inferior cropland under CRP. Surpluses continued to mount due to the slippage factors noted and to statutory limits on the minimum size of specific crop quotas. The U.S. Congress rejected industry-wide mandatory controls in 1962. The next year the government offered wheat farmers the opportunity to accept tight mandatory allotments coupled with high support prices versus free markets. Wheat farmers rejected controls in a hard fought national referendum in 1963.

The government deemed that farmers should not have free markets, however, and enacted voluntary short-term diversion programs whereby each farmer annually could choose to divert part of his land to soil conserving uses in return for price support and payments from the government. Such newly dominant short-term area diversion, of minimal size in previous decades, grew large and averaged 52 million acres in the 1960s, then reached the high-water mark of 78 million acres in 1983. Problems engendered by that 1983 diversion coupled with drought in the same year prompted a reexamination of commodity programs. Critics observed that voluntary area diversion programs were expensive for taxpayers. Furthermore, such programs, by raising commodity prices, lost markets to cheaper substitutes (for example, cotton to synthetics) and to foreign competition. Agribusiness firms that supply farm inputs and process and market farm products thrive on farms’ raw material volume—and they were not getting volume. Livestock producers as well as food consumers were hurt by feed costs inflated by supply controls.

These and other factors led Congress to end most supply controls in the Freedom to Farm bill of 1996. By 2007, supply control remained only under the Conservation Reserve Program (for environmental purposes) and on a minor crop, sugar. The demand for farm output had become elastic due to a large biofuels market. Because quotas reduce farm income when demand is elastic, they are an anachronism of an earlier era.

Termination of controls pleased consumers, agribusiness firms, and livestock producers, but reliance on payments without supply controls introduced new problems. Payments without controls induce farm output to exceed levels in an unregulated market. Whereas programs prior to 1996 cut production by approximately 5 percent from unregulated competitive market levels in the 1960s and 1980s and lesser amounts in other years, the 1996 and 2002 farm bills without supply management raised farm output an estimated 3 percent over competitive market levels. Part of that excess production is being dumped on international markets. Thus, the United States has shifted from World Trade Organization (WTO) acceptable blue box policies (that support farm income but control production) to less acceptable amber box policies (that expand output and exports above competitive market levels). Supply control programs are fatally flawed and are dead, but other, current government programs to support farm income in the United States remain problematic.

QUOTA SYSTEMS
A quota system is one of two different ways in which a policy of affirmative action may be implemented; it is the alternative to a system of preferential boosts. Under an affirmative action policy, membership in an identity group
recognized as marginalized and underrepresented increases one’s chances of being selected to a desirable position—for example, admission into a prestigious educational institution, or employment in a respected organization. The increased access is accomplished under a quota system by reserving a certain share of the available positions for members of the relevant group, thus dividing the overall selection process into two separate competitions. Under a system of preferential boosts, by contrast, there is a single competition for access to the available positions, but some additional favorable consideration is given to group members in evaluating individual qualifications and thereby determining applicant rankings.

During the early period in which affirmative action policies were implemented in the United States—from the mid-1960s through the 1970s—quota systems were not uncommon, though affirmative action policies more often took the form of preferential boosts. In India, however, affirmative action has mainly taken the form of quota systems. In other countries where affirmative action is practiced, one can find varying combinations of the two systems.

Under a quota system, the number of available positions reserved for members of a marginalized identity group in a separate competition is most often set equal to the proportion of that group in the overall population of the country (or the relevant region or locality). Such proportionality need not necessarily, however, characterize a quota system of affirmative action; the number of reserved positions may be set at any level. Separate quotas and competitions may of course be established for members of more than one identity group. Whatever the criteria for ranking applicants, these criteria are applied separately to each group of applicants, and the highest-ranking applicants in each group are selected until the available positions are filled.

Under a quota system, the number of selected members of any group targeted by affirmative action will equal the size of the quota for that group—unless fewer group applicants actually apply. A variant of this kind of selection process is one that excludes from the reserved quota those applicants whose qualifications irrespective of group membership enable them to be selected in competition with all other applicants. In this case, all the group applicants who are selected to reserved seats rank lower, by the relevant ranking criteria, than those selected in the general competition, and the overall number of group applicants selected may well exceed the quota reserved for them.

A preferential boost system is applied somewhat differently to quantitative and to qualitative selection procedures. In a quantitative selection procedure, an applicant’s qualifications are summarized in an overall point score in order to determine his or her position in the rank order, and the preferential boost takes the form of a certain number of additional points credited to applicants from the targeted group. In the case of a qualitative selection procedure, a variety of applicant qualifications are taken into account but not formally aggregated into a single overall point score. In this case, the preferential boost takes a less precise form; for example, applicants from the targeted group could be viewed in a rosier light or given extra credit for signs of unrealized potential. Different degrees of preferential boost may of course be given to applicants from different groups. In any kind of preferential-boost system, one cannot be certain in advance how many applicants from each group will be selected.

The difference between a quota system and a preferential-boost system is not as great as it may first appear. Corresponding to a quota system that selects any given number of targeted group applicants for a particular position, there is bound to be some amount of preferential boost that leads to the same outcome. In the case of a selection process in which applicants’ qualifications are summarized in a single point score, the amount of preferential boost that would do so is the number of points needed to bring the marginal group applicant’s score up to the level that would make him or her the last applicant admitted in the general competition. (There is one minor exception to this rule: if the last applicant selected to fill a quota has qualifications equal to those of one or more of the top applicants who failed to be selected, then a preferential-boost system would have to either accept or reject all of the marginal applicants with equal qualifications.)

Notwithstanding the formal correspondence between quota and preferential-boost systems, there remains a substantive difference between the two systems insofar as the parameters of each kind of system—the size of the quota or the amount of the preferential boost—are held constant for a period of time. A preferential-boost system assures that the gap in conventional qualifications between targeted group applicants selected and other applicants selected does not vary much over time, while the number of the targeted group applicants selected will in all likelihood vary from one competition to the next. A quota system assures that the number (or the proportion) of targeted group applicants selected will remain constant, unless the quota is not filled, while the gap in conventional qualifications will likely vary considerably over time.

In practice, quota systems are often constrained by specification of minimum conventional qualifications (e.g., a minimum qualifying score) below which targeted group applicants will be rejected, even if their quota is not filled. Whenever such a minimum conventional qualifications requirement serves to keep the number of accepted applicants below or equal to the quota, this kind of con-
strained quota system has the same effect as a preferential-boost system in which the size of the preferential boost is equal to the gap between the minimum conventional qualifications required of a successful targeted applicant and the conventional qualifications of the last applicant admitted in the general competition. (If and when the preferential boost implied by a minimum qualifications requirement in a constrained quota system is not binding—that is, if it alone would allow more applicants to be selected than the size of the quota—then there is, of course, a difference in outcome as between the constrained quota system and the corresponding preferential-boost system.)

A pure quota system is considerably more arbitrary than either a constrained quota system or a preferential-boost system of affirmative action. By focusing on a target number (or proportion) of group applicants to be selected, a pure quota system ignores problems likely to arise if the conventional qualifications gap between targeted group and other applicants selected becomes substantial. At the same time, however, it should be clear that the choice among a pure quota system, a constrained quota system, and a preferential-boost system is not the most critical choice for an affirmative action policy. Arguably the most important factor is the size of the explicit or implicit preferential boost involved in the policy, for this will affect the likelihood that affirmative action beneficiaries can succeed in performing well in the positions to which they have gained access.

QUOTAS

Quotas represent one method available to policymakers as a structural remedy for political or economic inequality. Put most succinctly, quotas have traditionally emerged from pragmatic discussions regarding the implementation of legislation or constitutional mandates to pursue equality among citizens. While citizens across nations have traditionally endorsed the political value of equality, there have been long-standing debates at the local, national, and international levels about the role of government in establishing or protecting citizens’ equality.

Contemporary debates about quotas emerge most frequently in the context of affirmative action policies. Affirmative action policies are premised on the belief that government must not simply protect citizens from invidious discrimination but must also take “affirmative steps,” as U.S. president Lyndon B. Johnson stated in his 1965 Executive Order 11246, to ensure that citizens have equal opportunity to obtain jobs in a labor market with a history of pervasive discrimination. Quotas have emerged around the world as one method to pursue and achieve equality in two ways: equality of opportunity to compete for jobs, education, or political power; and equality of outcome—the successful acquisition of such jobs, education, or political power.

One common use of quotas has enhanced the political power of women in legislatures around the world. Many parliamentary democracies have implemented quotas of women to stand for election, including Germany, France, Belgium, Bolivia, Rwanda, and Palestine. Such quotas have produced greater female representation in parliaments and changes in public policy and legislation that have an impact upon women’s well-being. These quotas, while controversial at the time of implementation, seem relatively stable and unlikely to change in the foreseeable future.

The use of quotas in other sectors of government policy continues to be much more controversial as they attempt to enhance equality among various lines of difference in political society. Nigeria, at the time of its independence in 1979, attempted to counteract the ethnic inequality that was a legacy of colonialism by instituting policies of “ethnic balancing,” many including hard numerical quotas for admissions into higher education and civil-service hiring. Yet ethnic tensions over access to wealth and ethnoreligious differences continue regularly to erupt into violence. Similarly, India included some forms of affirmative action at the time of its independence from Britain in 1947, yet political and economic inequality remains widespread in the world’s largest democracy. The “reservation system,” as India’s quota system is known, sets numerical percentages as targets for the inclusion of lower-caste minorities. Despite its constitutional legitimacy, implementation remains uneven. For this and other reasons, some target quotas go unfulfilled each year. When framed as a policy of racial or ethnic incorporation, quotas remain subject to legal challenge and outright invalidation, as occurred in the United States.

The U.S. policy of affirmative action emerged out of the modern civil rights movement of the mid-twentieth century and has moved away from “hiring goals” as quotas into a still-controversial system of preferential boosts to women and minority candidates for federal contracts, jobs, and college admission. Presidents John F. Kennedy,
Lyndon B. Johnson, and Richard Nixon together were responsible for affirmative action's evolution into a system of quotas. Kennedy first established a Presidential Committee on Equal Employment Opportunity, chaired by then–vice president Johnson, which focused on a comprehensive remedy to racial inequality by focusing on both protecting black and other minority citizens from discrimination and taking positive steps to encourage greater access to fair employment and education. These two policy arenas—education and employment—became primary battlegrounds for the implementation of affirmative action in the United States.

Initially the executive orders of Johnson (1965, 1968) and Nixon (1970, 1971) focused on two aspects of affirmative action implementation: time and scope. As well, both presidents’ administrations started with oversight of corporations that were federal contractors, and then sought further expansion of the policy in the private sector. Goals and timetables emerged as methods of enforcing compliance with both the letter and spirit of antidiscrimination laws. “Hiring goals” were set in cases where there was significant underutilization of certain racial groups in an industrial sector such as construction, and “admissions goals” were set in the domain of higher education. In the implementation of programs to achieve such goals, quotas were set as targets so that employers and educational institutions could demonstrate that they were taking the aforementioned affirmative steps.

These quotas were almost immediately challenged in court by white majority individuals who considered such programs a direct threat to their access to employment and higher education opportunities. The Supreme Court has spent a significant amount of time over the past forty years attempting to regulate the constitutionality of programs designed to implement the protection and promotion of equality. The court first contended with the Civil Rights Act of 1964, which created the Equal Employment Opportunity Commission as a federal agency charged with the oversight of public and private employers’ policies to prevent discrimination. In *Griggs v. Duke Power* (1971), the Court developed the theory of disparate impact, allowing the definition of discrimination to expand to situations where malicious intent was not necessarily a factor. Enforced corrective action such as hiring goals were permissible in situations where a definitive mismatch existed between the availability of minority workers and their presence in a particular occupation. Later, in *United Steelworkers of America v. Weber* (1979), the Supreme Court allowed voluntary agreements, including quotas reserving half of all craft training positions for African Americans until the percentage of African American workers in the sector matched the percentage in the local labor force. This decision is consistent with the underlying assumption that affirmative action in general is a time-bound policy; such policies will be obsolete once equality is achieved.

The Court also had a major impact on the scope of affirmative action programs. In 1978 the Court strictly limited the use of quotas as a tool of affirmative action programs in *Regents of the University of California v. Bakke*. Allan Bakke, a white applicant to the University of California at Davis medical school, successfully sued to remove the “hard” quota of reserving sixteen seats in each incoming first-year class for racial minorities. While the Court refused to allow this kind of quota, it continued to allow the use of race in a more vague way, “as a plus,” in admissions decisions. Quotas were also restricted in terms of the types of actions employers could take to pursue them. In two cases—*Firefighters v. Stotts* (1984) and *Wygant v. Jackson Board of Education* (1986)—the Court refused to allow employers to take jobs away from whites via layoffs in order to increase the number of minority hires.

During this same period scholars have hotly debated both whether quotas are a just form of implementing affirmative action and chronicled the trajectory of marginalized groups who have been targeted by such programs. In elite levels of higher education, African Americans have been determined to benefit greatly from admissions policies that include affirmative action—whether quotas or more loosely defined “goals.” On the other hand, though such policies have vastly contributed to the expansion of the black middle class, the persistently poor who have been left out of such benefits have become more economically insecure and isolated from the economic and political benefits of stable communities. As well, although little evidence suggests that affirmative action has produced “reverse discrimination” in the employment sector, the lack of structural investment in higher education over the past forty years and the emerging baby boomlet population have produced greater competition for a relatively stable number of college admissions slots in the United States, increasing public anxiety about affirmative action in general and political resistance to quotas of any kind—Supreme Court sanctioned or not.

Most recently the Supreme Court has continued to uphold the idea that the time for race to be considered a factor in college admissions and employment continues, despite numerous restrictions on the scope. In *Grutter v. Bollinger* (2003), Justice Sandra Day O’Connor, author of the majority opinion, restated the idea of a time limit to policies such as the constitutionally permissible law school admissions process. It is clear from the docket of the Court, however, that the scope of such policies is ever changing, and given political resistance to quotas in col-
college admissions, their eventual reinstatement is highly unlikely in the United States.

The experience of the United States with quotas varies from that of other countries in terms of scope, policy domain, and timetable. While other nations have successfully implemented quotas to ensure proportional representation of women in their lawmakers, the winner-takes-all quality of the U.S. electoral context makes such quotas more difficult, though not impossible, to implement. On the other hand, compared to such countries as France and Great Britain, which have both struggled to address racial inequality through either color-blind means or race-conscious means such as quotas, the United States spent more time during the mid-twentieth century directly confronting the lack of minority incorporation through various pieces of state and federal legislation.

While it is clear that persistent inequality is a challenge for nearly every country in the world, the responses to such inequality through the policy remedy of quotas has had mixed results and varying levels of political will to enforce them. As well, the scholarly analysis of such policies has not settled on a conventional wisdom as to their efficacy in producing the goal to which almost all of the quota programs aspire: equality among all citizens.

QUOTAS, TRADE

Trade quotas are upper limits on the quantity of goods shipped between two nations in a particular category, for example, men’s shirts. An export quota is administered by customs officials in the export nation, while import quotas are administered by the import nation. Prospective exporters or importers must first obtain a license to ship an agreed quantity, such as one unit. In practice many export quotas are set up at the request of importing nations, in which case they are voluntary export quotas (VERs). The most prominent example of VERs is the Multifibre Arrangement (MFA) that lapsed in 2005 and that set bilateral export quotas for textile and apparel trade, affecting some 10 percent of the value of trade of rich countries.

Quotas act similarly to tariffs in that trade is reduced, domestic prices are driven up, and exporter prices are driven down. In one very special case, quotas are fully equivalent to tariffs. The equivalence case requires that the importing country set the quota and that it sell the licenses to import at a competitive auction, thereby obtaining the revenue as it would with a tariff. When other qualifications are met, the price paid for a one-unit license is equivalent to a tariff, volume of trade and domestic and export nation prices are the same, and equivalence prevails.

QUOTAS VERSUS TARIFFS

Quotas in practice are more inefficient than tariffs. First, quotas strengthen monopoly power. For example, a sole domestic firm becomes a monopoly in its home when foreign firms are limited to a fixed quantity of sales whereas with a tariff, that firm potentially competes with many firms. Monopoly power raises prices above cost and thus imposes a loss on the economy.

Quotas are also inherently highly discriminatory, which adds to their cost. Discrimination arises because quotas are set individually for trade partners and for product lines. Even if the quotas initially are associated with uniform tariff equivalents, changes in economic conditions introduce nonuniformity. This produces dramatic discrimination across countries. Moreover, across product lines within a country, regulations typically prevent resale of quota licenses from low-payoff to high-payoff lines of sale, similarly preventing market forces from achieving nondiscrimination. Nations also use quotas to discriminate in favor of allies or against enemies, as with the U.S. sugar quota, which allows imports from high-cost Philippines and excludes low-cost Cuba.

Quotas may increase fluctuations in prices compared with tariffs, and this is costly. A fixed specific tariff will permit fluctuating amounts of trade when there are shocks to foreign supply or domestic demand. The average vol-
The volume of trade anticipated should be compared with a fixed quota of the average amount. The fixed quota will produce fluctuating tariff equivalents, which in effect discriminates across situations (states of nature) with different realized shocks. This discrimination is costly: It is more efficient to have more trade in high-tariff-equivalent states and less trade in low-tariff-equivalent states. The tariff accomplishes this perfectly compared with the quota.

The allocation of quota licenses is a potent cause of corruption, imposing further costs on the economy as resources are diverted from production to the pursuit of quota licenses: Before its reforms of the 1990s, India's government was often called "the license Raj."

POLITICAL ECONOMY OF QUOTAS

Why have quotas been used when tariffs can also provide benefits to import-competing interests, apparently at lower cost? There must be some political advantage of quotas over tariffs in cases where they are used. Quotas are less transparent than tariffs because calculation of tax equivalents requires data on comparable domestic and foreign prices. The lack of price data often means no one outside the most closely concerned parties knows how costly the quota is. This may permit import-competing interests to obtain tighter limits on imports than they could obtain from tariffs. Because beneficiaries provide political support to politicians who set quotas, both the government and interest groups may gain from choosing quotas over tariffs.

An apparent disadvantage of quotas relative to tariffs is that the government's potential tariff revenue is dissipated as quota rent earned by the license holders. The apparent disadvantage may, however, be a political advantage. First, with a VER, the quota rent typically gets awarded to foreign exporters who are initially being restricted in their access to the market. This compensates the foreigners for their loss and eases the problem of international trade relations with the foreign government. (This advantage is temporary. Later on, the VER will exclude exporters from other foreign countries and complicate trade relations with their governments.) Second, license holders are a very easily identified group of beneficiaries—easier to squeeze for political support than import-competing producers who may be hard to identify.

The apparent political advantage of quotas seems to argue that they should be very widespread. Politicians can play mutually beneficial games with producer groups in setting up market-share arrangements all over the international trading economy. Thus, limits on their use to a few areas of the world economy poses an important puzzle. To illustrate the importance of the puzzle, consider the MFA set of VERs that, until recently, controlled some 10 per cent of world trade. The MFA began in the 1950s and was gradually extended to cover more products and countries, so it looked durable. Yet the Uruguay Round of multilateral trade negotiations set an end date in January 2005. Despite the reversion to a temporary extension of VERs on China in fall 2005, the end of the MFA seems to be accomplished. Political economy should be able to say why. Moreover, political economy should be able to explain the use of tariffs as opposed to quotas in many other product categories.

QUOTATIONS FROM CHAIRMAN MAO

SEE *Little Red Book.*
International Encyclopedia of the Social Sciences, 2nd edition
RABIN, YITZHAK

1922–1995

At a time when Israel’s global economic and political prominence was on the rise, the nation’s prime minister, Yitzhak Rabin, was tragically gunned down. The three shots fired into Rabin’s back on the night of November 4, 1995, also pierced through a newly emerging Israel. As Israel began to forge significant political bonds with its Arab neighbors after years of territorial conflict, an Israeli law student, Yigal Amir, assassinated Rabin out of religious conviction. Rabin’s premature death left questions as to whether or not his objectives for a peaceful, economically strong Israel would be fully realized. This article discusses Rabin’s political and societal contributions to Israel, his relationship with Palestine, and the impact of his untimely death on Israeli politics and its relations with Palestine.

During Rabin’s early years, Israel struggled for national independence. Rabin was born in Jerusalem on March 1, 1922. A little over twenty years later, Rabin fought in the 1948 War of Independence, from which the Jewish population in Palestine could claim Israel as an official state. In 1968, Israel successfully fought against Egypt, Syria, and Jordan during the Six Day War, in which it gained control of the Gaza Strip, the Sinai Peninsula, the West Bank, and the Golan Heights.

Not long after, Rabin entered politics with minimal political experience. In 1974, the incumbent prime minister, Golda Meir of the Israeli Labor Party, stepped down after vociferous public calls for her resignation after Israel’s failure in the Yom Kippur War of 1973. Israel suffered a large number of casualties and the loss of limited territory in the Sinai Peninsula to Egypt and Syria during this war. Since Rabin was free from blame, he won the election for prime minister and took the oath of office on June 3, 1974. He faced numerous challenges as a political leader during a tumultuous time in Middle East history.

As prime minister from 1974 to 1977, Rabin contributed greatly to Israel in both the domestic and international arenas. He strategically forged a closer relationship with the White House and the U.S. State Department, a process that began during his tenure as Israeli Ambassador to the United States. This relationship was made evident when Richard Nixon became the first U.S. president to visit Israel. The visit was also a way for Nixon to resurrect his falling public stature during the Watergate trials, according to Rabin’s memoirs. This bond became significant as Rabin sought and garnered U.S. support for arms sales to Israel. Rabin also succeeded in finalizing a 1975 interim agreement with Egypt, in which Israel agreed to pull back from the Sinai Peninsula.

Rabin exhibited more skill in his second term as prime minister, from 1992 until his assassination in 1995. Israel and Palestine remained in conflict over the establishment of Israel as a separate state. Yet Rabin and Yasser Arafat, the leader of the Palestinian Liberation Organization (PLO), signed the Declaration of Principles (DOP), which aimed to terminate Israel’s occupation of the Gaza Strip and the West Bank. The Jewish and Arab leaders later signed the Oslo II agreement, in which Israel agreed to withdraw from seven West Bank towns and the Palestinians agreed to hold elections. The historically significant cooperation between the two leaders created opportunities for political and economic ties with the rest of the Middle East and nonregional states.
The Arab-Israeli tensions resulted in divisions within Israel itself. Rabin sought to resolve Israel’s conflicts with its Arab neighbors, especially Palestine, through political negotiation. However, some Jewish citizens such as Amir felt betrayed by the Oslo II accords. Amir saw the agreement as handing over land given to the Jews by God to Palestine. He felt that what he perceived as betrayal could only be rectified through murdering Rabin.

A focus on the free market contributed to Israel’s economic growth. Israel’s economic policy shifted away from socialist ideology towards a liberal economic policy, and in the early 1990s Israel experienced an annual growth rate of over 5.5 percent. At the same time, unemployment dropped below 7 percent. Israel’s economic stability attracted more foreign investment.

Ultimately, Rabin’s premature death had a long-lasting effect on Israel’s relationship with the rest of the Middle East. Many years later, Israel still struggles with questions of its identity, democratic order, the future of occupied territories, and the chance for peace with Palestine.

RACE

The concept of race as a categorization system for human beings did not exist formally until the late eighteenth century. Most analysts (e.g., Feagin and Feagin 1999; Allen 1994; Roediger 1991; Omi and Winant 1994) have linked the inception of the biologically based idea of distinct races of human beings to European colonization of the New World. Although prior to this time human beings certainly distinguished between themselves in many ways, these distinctions tended to be based upon tribal, clan, ethnic, or national differences that stemmed from place of residence/territory or shared belief systems rather than on innate, genetic characteristics. However, as capitalist-based exploitation of certain (often darker-skinned) groups began in the form of chattel slavery and other abuses of humanity, those in power began turning to science as a way to rationalize the oppressive conditions to which these groups were consigned. The rush to develop these pseudoscientific claims might have been spawned in part by the need of the colonizers to assuage their guilt and to resolve the cognitive dissonance and contradictions evident in rising new societies that prided themselves on freedom and democracy even as they relegated certain groups in their societies to a nonfree, even subhuman status (Horsman 1997). While the “science” that developed the idea of race is certainly discredited by today’s standards, the social ramifications of humans having separated themselves into races still remain firmly intact. As the Thomas theorem once stated, “when men define situations as real, they are real in their consequences” (Thomas and Thomas 1928, p. 572). Thus, although the idea of race as a classification system of human beings is what social scientists call socially constructed rather than biologically based, it still is an enduring category of social analysis. It is so not because of its genetic or biological basis, but because of the power it has wielded as an idea to create dividing lines between different classes of human beings across the globe (Graves 2004).

BEFORE RACE

Prior to the eighteenth century, human beings were recognizing differences between themselves as they crossed national and continental borders in exploration and trade. Sometimes these differences would be reflected upon positively and at others, negatively, especially when groups clashed over territory and power. For example, there are Biblical writings where African kingdoms and Jewish kingdoms are regarded as allies of generally equal worth and status. And in Greek and Roman periods, these two societies expressed a great respect for the learning they gleaned from African cultural developments. Even as occasional negative images of blackness (associated with sin, devil, and non-Christianity) were expressed, “these views were never developed into a broad color consciousness viewing Africans as a greatly inferior species” (Feagin 2000, p. 71). Thus, although human beings reflected upon their own differences as they made contact with each other throughout time, there was generally a mix of negative and positive imagery, and prior to the idea of race, no discussion of an altogether inferior or superior species attached to physical differences yet existed.

From the 1400s to the 1600s, as colonization and enslavement expanded, the Spanish and other Europeans began to use consistently negative language to describe the African human beings they enslaved. This pattern was coupled with positive evaluations of their own group. However, these evaluations still did not amount to explic-
itly racial designations. The Europeans’ negative assessments of Africans at this point were rooted in cultural and religious differences rather than in any biological, unchanging facts of their physical chemistry. For instance, Europeans described themselves as rational and civilized while they described Africans as uncivilized and uncontrolled. Further, the Africans not being Christian resulted in Europeans characterizing them as “heathens,” and later in North America, European settlers used the same line of thinking toward the Native Americans (Feagin 2000; Takaki 1993). In fact, in the 1600s, a European named François Bernier (1625–1688) even developed a hierarchy of groups ranking them from the most primitive and civilized to the least, placing Europeans at the top and Africans at the bottom (Feagin and Feagin 1999).

However ethnocentric and biased these claims were, they were based upon the assumption that these were cultural differences emanating from shared, learned beliefs rather than body composition or other unchangeable biological inheritances. Indeed, in the case of the Native Americans, for a brief time, the colonists in power considered the possibility that Native Americans could be civilized and thus considered equal by converting them to Christianity (Takaki 1993). These positions acknowledging a common human capacity for acquiring knowledge across all skin color gradations (even as it was perceived as underutilized or underdeveloped for some) still ran counter to later notions of biologically grounded races.

RACE AS IDEOLOGY AND SOCIAL RELATIONSHIP

Several scholars have identified the conception of human races as a key part of the development of a racist ideology (e.g., Feagin 2000; Yetman 2004). An ideology is a belief system intended to rationalize and justify existing social arrangements. In this way the concept of race is a decisively social concept because it is not observed as existing independent of the “racialized social systems” (Bonilla-Silva 1997) that hold it in place. Feagin identifies three dynamics that crystallized by the late 1700s to result in a clearly racist (as opposed to nationalist or cultural) ideology: “(1) an accent on physically and biologically distinctive categories called ‘races’; (2) an emphasis on ‘race’ as the primary determinant of a group’s essential personality and cultural traits; and (3) a hierarchy of superior and inferior racial groups” (Feagin 2000, p. 79). Thus, at this point in history, no longer are human differences attributed first and foremost to national, regional, and cultural variations. Instead, they become perceived in a biologically determined (static, unchanging) way, and the differences begin to be encoded into hierarchical categorization schemas that connote superior and inferior species of human beings.

The language of race as a pseudobiological category of humans emerged first in the 1770s with the German philosopher Immanuel Kant (1724–1804). As noted by Emmanuel C. Eze in his 1997 publication, Kant’s categorization hierarchy for “races of mankind” was laid out as follows:

- Stem genus, white brunette;
- First race, very blond (northern Europe), of damp cold;
- Second race, copper-red (America), of dry cold;
- Third race, black (Senegambia), of dry heat;
- Fourth race, olive-yellow (Indians), of dry heat.

Roughly two decades later, another German scholar (of human anatomy) named Johann Blumenbach (1752–1840) ventured into similar territory of racial hierarchies founded on what he viewed as biological premises. Ivan Hannaford noted in his 1996 work that Blumenbach’s categories were conceptualized in the following order (top to bottom; superior to inferior):

- Caucasians (Europeans)
- Mongolians (Asians)
- Ethiopians (Africans)
- Americans (Native Americans)
- Malays (Polynesians)

Blumenbach was the one who coined the term Caucasian simply because he felt the Europeans he observed in the Caucasus mountains were the most beautiful, and he erroneously concluded that the first human remains were found there (Gould 1994). Yet the power of this pseudoscience remains in contemporary consciousness, as some modern-day Americans who view themselves as white, for example, refer to themselves as Caucasian, even when their genealogy hails from nowhere near the Caucasus mountains from which this category got its name. It is work like this that laid the groundwork for the centuries that followed, with human beings across the globe viewing themselves as members of distinct racial groups. These groupings were never just nominal categories; they were always hierarchically arranged and structured by dominance (Hall 1980).

An important point to note about these racial categories is that they did not just come to have meaning simply because a couple of scholars penned these categorizations systems and they attained popularity. They were reified because racialized social systems were structured around them. That is, the social relations of the day mirrored the order that the categories suggested. They would not have acquired such powerful social meaning.
without the systems that held them in place. Thus, one way to conceptualize race is a way of relating within a particular racial social system. Since its inception in the eighteenth century, the meaning of any particular race changes over time and is culturally specific. A single individual could be deemed one race in one society but move or travel to a different society (or even between states in the same society, as in the case of the United States) and be categorized as a different race. Its basis for meaning resides in a particular society’s racialized social system and not within an individual body. Some social scientists use the term reification to describe this process of turning a social relationship into a thing in and of itself. As noted by Margaret Radin, once reified, race “acquires a ‘phantom objectivity,’ an autonomy that seems so strictly rational and all-embracing as to conceal every trace of its fundamental nature: the relation between people” (Harris 1998, p. 107).

USING BLOOD TO DETERMINE RACE

Although the social distinction of a race of human beings was often based upon physical characteristics, the question of which physical characteristics were used to determine race and in what proportion has varied greatly across cultures and across time. These distinctions are usually set by those in power for a distinctly political purpose. For example, in the United States, the so-called “one-drop rule” predominated for all of the nineteenth and well into the twentieth century. This rule stated that an individual having even a distant ancestor who was categorized as black (conceived as one drop of black blood) also made that individual black as well. It is important to note that this determination was not, of course, made from blood testing but rather from knowledge of the individual’s family tree and the racial categorizations (socially) attached to each member. This rule served the political purpose of limiting the numbers of persons who could cross the racial dividing line to become white and enjoy all the perquisites and privileges thereof. In the United States, chattel slavery was officially permitted and governmentally sanctioned until the Emancipation Proclamation of 1865. However, shortly into the nineteenth century, no further importation of slaves from overseas was permitted under the Constitution. Thus, it was convenient for the white patriarchal powers of the country that any offspring resulting from the sexual exploitation of their black female slaves (even though these children were also half white) would still be considered their own property and not eligible for freedom (Graves 2004). However, even after slavery was abolished, individuals who were defined as black by the one drop rule had severely curtailed rights, and many lived in a status that was similar to slavery except in name, due to sharecropping, the convict lease system, and white terrorism holding all of this in place.

According to court records, in order to escape this awful fate, many individuals attempted to remove their black racial categorizations by way of the law. What fraction of black blood was needed in order to categorize one as black? In Louisiana, for example, it was one-32nd of “black blood” that made someone into “black.” The U.S. Census identified the racial categories of Negro, Mulatto (one-half black blood), Quadroon (one-fourth black blood) and Octoroon (one-eighth black blood) as late as 1890 (Lee 1993). When individuals were not able to attain legal freedom from blackness but were somewhat light-skinned, they sometimes participated in passing by portraying themselves as white. It is notable that such passing activities almost always occur when someone categorized as an “inferior” race attempts to pass as a member of the “superior” race and not the other way around. This indicates how race is explicitly hierarchical and designed to keep dividing lines between who does and who does not receive the full rights and privileges of citizenship in any given society.

In the contemporary context in the United States, the pseudoscientific notion of a blood quantum (one-fourth) has to be proven in order for citizens to be able to racially categorize themselves as American Indian. Additionally, this one-fourth fraction of Native American blood must be with a tribe that is officially acknowledged and sanctioned by the federal government (Thornton 2001). In early 2006 there were about 569 such tribes (Taylor 2006). In order to get one’s tribe recognized by the government, one goes through a lengthy process of forms and bureaucracy, which is sometimes a challenge for older members of a tribe struggling with the level of literacy in bureaucratic language that these forms require. Thus, there are probably many more U.S. citizens who consider themselves to have Native American ancestry than are officially counted by the federal government, who estimates they are only about 1 percent of the total population. This official count, estimated by the U.S. Census, experienced a sizable increase between the 1960 and 1990 censuses. Researchers pointed out that this “growth” in the American Indian population was not due to increased births, and certainly not to migration, but to the increase in individuals who decided to categorize themselves as Native American (Thornton 2001; Nagel 1995). This finding again underscores the socially constructed basis of race.

RELIGION, ECONOMICS, AND SHARED STIGMA AS RACE

While examining one’s family tree and ancestors is one way that societies go about determining who belongs in which race, occasionally, other factors are used. For exam-
ple, government officials sometimes transform religious groups into races. Adolf Hitler (1889–1945) during Nazi Germany spoke of the Jews as a race and structured gruesome genocidal public policy around this claim. Additionally, the U.S. Census records show that in 1930 and 1940, Hindu was given as a choice for racial categorization (Lee 1993). Besides these cases of religion being racialized, sometimes, one's social class is used as a marker for race. In Brazil there is a saying o dinheiro embranquece, which means “money whitens.” Because there are many mixtures of skin types in Brazil, skin tone combines with socioeconomic status to create the notion of race. For example, if a person is of a mixed skin tone but is dressed professionally and holds a prestigious position, that person may be considered white while a person with an even lighter skin tone who appears impoverished might be labeled black (Taylor 2006).

In a minority of cases, groups who are not in the majority racially sometimes come together to create a racial group and ask those in power to sanction it as a new race. For example, the pan-ethnic racial category of Asian and Pacific Islander (API) appeared on the U.S. Census for the first time in 1990 (Lee 1993). This race was created by bridging some major differences in terms of national origins, languages, and religions. In fact, the United States had a history of finding favor and disfavor with different ethnic groups that are now in the API category depending on the political and economic climate of the day. When the economy became saturated with Chinese laborers in the nineteenth century, the United States passed the Chinese Exclusion Act. At this time, it was more favorable to be Japanese. However, during World War II (1939–1945) when the federal government placed Japanese Americans (even those who were born and raised in the United States) into internment camps, it was more favorable to be Chinese. Despite these and many other cleavages between the groups that are now united in the API race, the groups came together under a specific political climate in the 1980s when the United States was experiencing an economic recession and some dominant rhetoric blamed a global Asian face for the job loss and downward mobility of those who considered themselves white. Thus, regardless of national origin, many API individuals began to be scapegoats and targets of white hostility and even vicious hate crimes (Espiritu 1992). Perceiving common issues of oppression shared across ethnic lines in the U.S. context was an important motivating factor in the creation of the API race.

Omi and Winant (1994) developed a theory of racial formation that underscores how racial categories such as the API are socially constructed, usually for political ends. Although in the majority of cases of racial formation the state uses its power to control what defines a race and who is allowed to claim membership within it, in a minority of cases (such as the API category), the initiative to construct a racial category comes “from below.” These minority individuals still have to find favor with the state in order to make their category official. In the case of the one-drop rule, many people were denied their legal efforts to challenge the state and become recategorized racially. But it is important to note that in the case of the one-drop rule, permission was being asked to join into the dominant group (whites) whereas the API group created a new category that did not upend or challenge the existing racial hierarchy. Similarly, in 2000, a group of individuals who considered themselves multiracial effectively lobbied to change U.S. Census procedure so that for the first time people could check more than one box to define their race. Again, this was a movement from below to create new racial possibilities, and it did not seek to challenge the dominance of the category white. The closer policing of the boundaries of whiteness by the state is indicative of how structured by dominance race is.

DETERMINING WHICH ETHNICITIES GET TO BE WHITE

Unlike ethnicities that are often directly linked to a particular continent, and usually a specific nation, the concept of race is an obviously socially constructed category due to its inability to be traced to any one geographic region. One cannot point to black or white on a map as one can with an ethnicity, such as Chinese, Japanese, Jamaican, Irish, or Mexican. This is particularly evident when studying the dominant category of whiteness. While some might equate the term white with a term such as European American, such terminology conceals how much whiteness has adapted to incorporate various non-European groups over time when it served the purpose of solidifying the material and ideological advantage of the category white in a particular area. For example, although people claiming either Chinese or Japanese ancestry are placed into the API category (usually known as Asian Americans) in the United States, during apartheid in South Africa, individuals with these two ethnicities had very different racial experiences. The Japanese were classified into the white category, enjoying the social privileges of the dominant group, while the Chinese were placed into the “colored” category. Although coloreds were not treated as poorly as those considered Africans, they nonetheless were well below whites on the racial hierarchy (Marger 2006). Thus, when it was crucial and beneficial for South Africa to maintain positive economic relations with Japan, it was not in their best interests to consign Japan’s citizens to second-class status. Treating the Japanese as whites meant that South African whites could still cash in on the material advantages that came from trading and doing business with the Japanese in an
increasingly globalized marketplace in which China was not yet a key player.

In the U.S. context, the Irish and the Jews are two examples of ethnic groups that, although still predominantly European, were not regarded as white upon arrival into the country and had to “earn” their incorporation into whiteness. In the early nineteenth century, the Irish arrived in a mass migration, escaping famine and British oppression. They had no kind of shared identity with the largely British white majority in the United States since the Irish saw the British as their oppressors. Furthermore, the Irish found themselves still excluded outright from many of the best jobs and were even targets of the exaggerated big-lipped, ruddy-skinned caricatures that students of history would typically associate with African Americans. Yet when the political question of the abolition of slavery reached front and center by the middle of the 1800s, the side that the Irish chose to take en masse would be an important deciding factor in whether they became incorporated into whiteness. To side with the slaves, they perceived, would consign them to the second-class citizenship they had just worked so hard to flee in their native land. In coming out decidedly antiblack abolitionist on the slavery question, already speaking the English language, and attaining access to some key positions in civic life (particularly in New York City), the Irish solidified their position into the dominant race, white, by the middle of the nineteenth century (Allen 1994; Roediger 1991; Takaki 1993).

The Jews also faced the kind of in-between racial status upon first arriving to the United States that the Chinese faced by being categorized as colored in South Africa. The immigrant Jews certainly were not as ostracized, disenfranchised, and terrorized as African Americans were, but they were not at first deemed worthy of receiving the full benefits of whiteness. They were excluded from most major universities and were victims of prejudices and ethnic slurs (Takaki 1993). Further illustrating the point that race is a relational category, it was the outright exclusion of blacks from the educational and housing benefits of the post-World War II GI Bill that catapulted Jews into middle-class status. Not unlike the situation of the upper class Brazilians, Jews gained the favor of whiteness by their newly acquired socioeconomic status during an economically prosperous era of U.S. history. This prosperity was generated in part by huge government subsidies for both college scholarships and home mortgages, which could be characterized as the nation’s first affirmative action program, giving all those deemed white a leg up over their African American counterparts. Although many blacks technically were eligible for these benefits due to their service in great numbers to the military during World War II, they were often unable to cash in on them when prejudiced southern commanders would give them dishonorable discharges for no particular legitimate reason. Moreover, since the Fair Housing Act was not passed until the late 1960s, it was perfectly legal for African Americans to be excluded from buying any of the quality housing to which those deemed white had full access. The events of this time period have been identified as the major factor contributing to the movement of Jewish Americans from nonwhite to white (Brodkin 1998).

STATE-CREATED CATEGORIES VERSUS PERSONAL IDENTITIES

While one’s state-defined race clearly plays a crucial role in whether one can access the full material benefits of a society, due to its explicitly hierarchical basis, it is also the case that individuals are not completely without agency in navigating their relationship to these racial categories. People all over the globe have always resisted their oppression in various ways. For example, a U.S. professional golfer named Tiger Woods resisted the society’s one-drop rule categorization of himself as African American and invented the term Cablinasian to encompass his Caucasian, black, Indian, and Asian heritage (Taylor 2006). Furthermore, there is a large group of U.S. citizens who think of themselves racially as Latino or Hispanic even though the nation’s census does not allow them the option of identifying this as their race (unless they write it in as “Other,” as many do). The census only includes the racial choices of White, Black/African American, Asian, Pacific Islander, Native American Indian, and Other but lists various Hispanic national origins under a separate ethnicity question. This structure actually encourages persons of Latino heritage to either identify as a white Hispanic or a black Hispanic (as 50% did in 2000), further reifying the country’s dichotomous black–white divide. Nonetheless, as this group of persons with Latino heritage in the United States grew exponentially by the advent of the twenty-first century, national conversations began to occur about the inadequacy of the state categories for race to adequately measure their experiences (Swarns 2004).

Because of the extreme occupational, residential, and social segregation that continues to exist in the United States, distinct cultural and ethnic patterns have come to be associated with these state-identified racial categories. For example, due to their exclusion from white churches, African Americans developed decisively different worship patterns even from those who shared their same denominations as Christians. Additionally, due to the many prohibitions during slavery of African Americans from socializing and congregating with each other, they also developed their own distinct linguistic patterns. Cultural developments and distinctions like these often lead to people talking about feeling (or not feeling) black, white,
Asian, and so on. France Winddance Twine found that some young women of African descent who had mixed parentage and grew up in affluent suburban communities stated that they did not feel black until they came to college campuses where they were not the only token minority and together with others developed a more politicized understanding of racial identity (Twine 1997). Conversely, many whites who subscribe to a colorblind racial ideology state that they do not feel white or see themselves as white at all (McKinney 2005; Bush 2004). Nonetheless, due to the sedimentation of racial inequality (Oliver and Shapiro 1995) where whites collectively transmit their “ill-gotten gains” from slavery collectively in the form of wealth to succeeding generations (Feagin 2000), these whites still gain a material advantage from being white even if they do not see themselves that way.

Beyond feeling culturally and emotionally linked (or not) to particular racial identities, some individuals may eschew state-created racial categories for other reasons. When perceiving that the dominant culture has a particular disdain for individuals of a certain race, new immigrants may seek to distance themselves from that racial categorization, especially when the dominant culture’s tendency is to lump them into that negatively perceived category. For example, some members of immigrant groups who would be classified as blacks in the United States, such as Samoans, West Indians, and Haitians, have been found to distance themselves from the racial category of black due to the pervasive antiblack stereotypes they encounter about such things as work ethic and dedication to education (Waters 1999). Similarly, sensing negative prejudices about Mexicans in the United States, some Cuban Americans and other South American Latinos have chosen to stress their national heritages over a more global racial identity as Hispanic (Fernandez-Kelly and Schauffler 1994). Although it is difficult to escape the systemic benefits or lack thereof of being deemed within a particular racial group (as a pseudoscientific birthright), individuals certainly do participate upon occasion in challenging, at least at the personal identity level, their affiliation with an assumed racial group.

SOCIAL CONSTRUCTION, MATERIAL REALITY

Race is not skin color, nor is it ethnic identity. It is not reducible to genetics. Indeed, there is much more genetic and physiological variation within the members of any given race than between individuals of different races. It has been estimated that the overlap between genetic material of people of any two racial groups is about 99 percent, so less than 1 percent of physiological differences can be explained by race (Lewontin 1996). Moreover, eventually, all genetic material of human beings traces back to Africa, where the earliest human remains were found (Feagin 2000). It has been established that any separate race (other than the human race) is not an actual scientific category and is, instead, a social construction. The assertion that race is a social construction, though, should not be confused with the notion that race is a complete fabrication only needing deconstruction (or simply ignoring/discrediting) to no longer be relevant. Even if governments decided to stop recording the racial categorizations of their citizens (as many outside of the United States have), race would still continue to be a fundamental organizing principle in society.

As has been demonstrated, the concept of race originated as an ideology meant to justify colonization and exploitation of people who happened to be, usually, darker-skinned than their exploiters. Material conditions between those who were eventually to be considered separate, superior/inferior races were already starkly unequal by the time the pseudoscientific category of race was formalized. Rigid laws enforcing the so-called superior racial group’s advantages and the so-called inferior group’s disadvantages continued for centuries. These chains have only been lifted, as of early 2006, for a few decades, and the material advantage/disadvantage gap has been so solidified that people’s ways of thinking, being, and doing are still very much tied to this way of relating called race. Moreover, the pseudoscientific claims of racial difference in intelligence, athletic/physical ability, and other characteristics are constantly resurfing into the present day. People are also finding other ways to further racialized understandings of the world without even mentioning race by using various code words and rhetorical strategies to camouflage what, in the end, has a very similar effect in organizing the social world into superior and inferior beings (Bonilla-Silva 2003).

Thus, regardless of how socially constructed race is, for better or for worse, society is stuck with its legacies. The rigid boundaries it was invented to enforce have created distinct cultures and ways of being. To even expect that these racial categories could eventually remain in society in a more benign way as nominal ways of distinguishing between separate but equally valued cultural groups is to confuse race with ethnicity. Race’s raison d’etre was never solely to distinguish between various national and cultural heritages; it was always proposed in a hierarchical order, with attached value judgments of superior/inferior and corresponding material advantages or disadvantages. Until society addresses the material foundations of race and rectifies the resulting imbalances, simply deciding to erase race linguistically from the vocabulary will hardly get rid of it as a fundamental organizing principle of social life.

RACE AND ANTHROPOLOGY

The history of anthropology has been closely identified with the study of race. In the early twenty-first century the concept of race is highly contested among anthropologists, some of whom claim that it does not exist in either biology or society except as an objectionable, stigmatizing
fiction. Its problematic biological status has led some to assume a “no-race” stance that resonates with the color-blind ideology that has gained popularity in some segments of U.S. society. Color blindness denies the extent social significance and the experiential and institutional materiality of race, races, and racial inequalities.

Race is an ideologically charged and invidious social distinction (Berreman 1972). As a social and often legally codified classification, it is applied to populations presumed to share common physical, biological, or natural attributes believed to be heritable. The “naturalizing” effect of many racial discourses translates into claims that the social disparities linked to racial divisions exist naturally rather than having emerged as a result of human practices and inventions. Due to the imprecision of what physical variation, biology, and nature actually mean and the slippage between culture and biology within any cultural context, race is difficult to define in a manner that clearly differentiates it from ethnicity, nationality, or even gender. The permanence and fixity conventionally associated with nature and biology are questionable due to “the human organism’s [and nature’s] constant state of change”—often in response to human interventions (Wade 2002, p. 6). A cross-cultural approach reveals that in certain parts of the world (e.g., Latin America) racial identification can shift, and the extent to which it is based on appearance, ancestry, or sociocultural status varies. Anthropological inquiry is rethinking and attempting to provide clearer operational definitions for the basic categories around which the social analysis of race has been built. Terms such as phenotype, nature, biology, blood, and heredity must be scrutinized in view of the unspoken assumptions underpinning them. Rethinking the parameters of race is being done, from different angles, in all of the discipline’s subfields: social and cultural anthropology, anthropological linguistics, archaeology (particularly historical archaeology), and biological anthropology (especially the specialty in which a critical biocultural approach is employed).

Although race has long been a gloss for human biological variation, they are not the same. During the eighteenth and nineteenth centuries along with the first half of the twentieth, the race concept was used to make sense of the diversity of human phenotypes, which were assumed to index fundamental biological and sociocultural differences. Biological variation is more complex than the physiognomic diacritics that came to signify race in the broad geographically based taxonomies formulated in 1735 by the Swedish botanist Carolus Linnaeus (1707–1778) and in 1795 by the German professor of medicine Johann Friedrich Blumenbach (1752–1840). Beneath the skin’s surface are differences of blood type and strings of DNA. However, genetic variation among human beings is small. Humans are 99.9 percent alike genetically, with most of the difference “invol[ing] modest degrees of variation in the frequency of shared genes” (IUAES). Most of this is within groups rather than between them. Socially targeted differences ignited the imagination of folk theorists and scientists, who drew on the popular consciousness to construct the formal typologies conferred the legitimacy of science.

Skin color, hair texture, and morphological traits were visible markers used to develop universal taxonomies for classifying human populations during the age of European exploration and colonial expansion. These differences were linked to social and moral characteristics that stereotyped and rank-ordered the world’s populations in a global hierarchy (Fluehr-Lobban 2005). These hierarchical classifications naturalized perceived cultural variation and culturalized what was defined as nature. They also justified the colonial expansion that gave rise to a modern world system of culture, power, and political economy in which privileged western Europeans exercised supremacy over the heterogeneous peoples, habitats, and resources of the world. These structures of domination were predicated on the land alienation, coerced labor, and repressive state policies that racialized colonial landscapes, with the transatlantic region playing a central role in the transfers of value that were a catalyst for the Industrial Revolution (Williams 1944; Wolf 1982). This momentous transition in social evolution occurred in the context of the transatlantic slave trade and related forms of enslavement established throughout the Americas.

Although color/phenotype prejudice preexisted the modern world system, race as a worldview (Smedley 2007) and material relation did not emerge until the “post-1400s western European racist order” (Sanjek 1994, p. 8). According to St. Clair Drake (1911–1990), skin-color prejudice and slavery converged for the first time in the New World’s colonies of exploitation where the conditions for racial slavery arose (Drake 1987). This transformation laid the foundation for a global racial hierarchy in which sub-Saharan Africans represented the most extreme variant of cultural and racial difference. The primitive savagery attributed to Africa and other peripheralized zones of the world system represented the binary opposite of western Europe’s purportedly advanced civilizations.

A chapter in the multinational history of racial typologies is that in which Count Arthur de Gobineau (1816–1882) elaborated the notion of the natural inequality of human races and Aryan supremacy in his Essai sur l’inégalité des races humaines (Essay on the Inequality of Human Races, 1851–1855). The part of this history that is usually omitted is that Joseph-Anténor Firmin (1850–1911), a Haitian who belonged to the Anthropology Society of Paris, wrote De l’égalité des races
humaines: Anthropologie positive (The Equality of the Human Races: Positivist Anthropology, 1885), a robust rebuttal and alternative approach to the study of humankind (Fluehr-Lobban 2005, pp. 110–116). Similar debates occurred in other national and regional contexts, including Latin America, where interpretations of Charles Darwin's (1809–1882) evolutionary theory were informed by cultural orientations significantly different from those of Anglo North America. The Anglo-dominant United States emphasized the permanence and mutual exclusivity of race and that whiteness was constructed along lines of purity. In Brazil and elsewhere in Latin America, whiteness was tied to the idea, goal, and social process of race mixing and its implicit ideal, whiten-ing—becoming white by marrying up the social scale or by acquiring wealth and assimilating socially valued cultural and linguistic characteristics.

Throughout the nineteenth and at least half of the twentieth centuries, scientific racism or racialism (Lieberman 2003) was espoused within theological and secular varieties of monogenesis and polygenesis. At the height of the antislavery movement, polygenists, claiming that a single genesis could not account for the diversity of the world's peoples, honed the technical capacity of phrenology and craniometry to measure differences. They also promulgated their research results through scientific outlets, popular culture, and political debate. Samuel T. Morton (1799–1851), Josiah Clark Nott (1804–1873), and George Gliddon (1809–1857), who constituted the core of the early American school of anthropology, attempted to substantiate the hierarchical ranking of the races, with the Caucasoid at the top, the Mongoloid in the middle, and the Negroid at the bottom. Louis Agassiz (1807–1873), a Harvard professor, supported their polygenetic findings and advised President Abraham Lincoln (1809–1865) that freed blacks were incapable of becoming the equals of whites. Later in the nineteenth and early twentieth centuries, bioculturalism developed along the lines of social Darwinism, couched in Darwinian categories but filtered through Spencerianism. These views underpinned the unilinear evolutionism of Edward B. Tylor (1832–1917) and the physical anthropology of Aleš Hrdlička (1869–1943), leaders in anthropology's professionalization. Anthropology's scientific racism also provided ideological fuel for the eugenics movement. Through sterilization and immigration restrictions, it aimed to limit the growth of poverty, criminality, and intellectual inferiority believed to be concentrated among African Americans, immigrants from southern and eastern Europe, and the poor. Eugenics laws developed in the United States were later used as models for population control policies in Nazi Germany. Also philanthropic support from the United States contributed to the rise of Nazi anthropology (Schafft 2004).

A paradigm shift occurred under the leadership of the Columbia University professor Franz Boas (1858–1942), whose research challenged the dominant perspectives on immigrants and other racialized segments of society. Conceptualizing race, language, and culture as distinct domains (Boas 1911, 1940), he influenced many colleagues and students, including Ruth Benedict (1887–1948), Margaret Mead (1901–1978), Melville Herskovits (1895–1963), Zora Neale Hurston (1891–1960), Ella Deloria (1888–1971), Dakota Sioux), and Ashley Montagu (1905–1999). Montagu (1942) insisted that race was a fallacy and advocated the alternative notions of genogroup and ethnic group. By World War II (1939–1945) Boasianism had become more widely accepted. It cleared the ground for major shifts in the 1960s, when race's biological status was refuted (Livingstone 1962). Many sociocultural anthropologists assumed that race was not useful for understanding social distinctions. This led to a silence concerning structural racism.

The Boasian agenda was not the only antiracist trajectory to influence anthropology. W. E. B. Du Bois (1868–1963) produced critical social analysis that in many respects paralleled Boasian thought (Baker 1998; Harrison 1992). He was part of a tradition of black racial vindication that contested biodeterminist ideas. Early African American anthropologists, trained in leading graduate departments but also influenced by Du Bois's noncanonical public intellectualism, often undertook antiracist scholarship, which entailed negotiating the tensions between mainstream disciplinary approaches and more critical interdisciplinary frameworks. The physical anthropologists Caroline Bond Day (1889–1948) and W. Montague Cobb (1904–1990) along with the social anthropologists W. Allison Davis (1902–1983) and St. Clair Drake exemplify this trend (Harrison and Harrison 1999). Davis and Drake, under W. Lloyd Warner's (1898–1970) supervision, provided important inputs into the collaboratively produced Deep South: A Social Anthropological Study of Race and Class (Davis et al. 1941). Drake and Horace Cayton's (1903–1970) Black Metropolis (1945), which became a race relations classic, combined the methods and analytical perspectives of anthropology and sociology. These books' receptions in anthropology were negligible.

After anthropology's “biological revolution,” when the discipline was largely silent about social race and racism, Marvin Harris (1927–2001), St. Clair Drake, Eleanor Leacock (1922–1987), Gerald Berreman, and John Ogbo (1939–2003) kept these issues alive, often bringing cross-cultural perspectives and data to bear on them. In the 1980s Virginia Dominguez (1986) and James W. Loewen (1988) explicated the social construction and dynamics of race, including how they related to

Since the early 1990s there has been an expanded interest in race (Harrison 1995, 2002). In good part this has arisen because of race’s heightened volatility in many parts of the world, especially under the conditions and outcomes of globalization: technologically mediated time-space compression, widening disparities in subsistence security and wealth, new migrations, transnational cultural citizenries, and diasporic identities. Sociocultural anthropologists have investigated the multiple histories and cultural dynamics of race, the persistence of its social significance, the shifts in its meanings, and its overt and covert modalities (Smedley 2007; Baker 1998). Neoracisms without races, the social censorship of talk about race and racism, and race’s intersections with gender and class have also captured anthropologists’ scrutiny and ethnographic gaze. Research is being undertaken in many parts of the world, from eastern Europe, where postcommunist restructuring has exacerbated discrimination against the region’s Roma (“Gypsies”), to the more paradigmatic settings of the United States, South Africa, and Brazil, which have long been a focus of debates over the varieties of racial formation (Scheffel 2005; Sheriff 2001; Wilson 2001).

A great deal of attention has been given to the social life of discourses that biologize or culturalize difference—that is, use notions of culture to produce racializing effects. Linguistic anthropologists have examined language practices that contribute to or resist the dynamics of racialization. Their approach to the social politics of language may lead them from explicit hate language to covert language whose efficacy is affected by indirect indexes or widely understood but never directly articulated nonreferential meanings (Hill 1998). Critical biocultural anthropologists explore the embodied experiences that affect human exposure to stress and susceptibility to diseases. In their view, race affects the internal and external workings of the body, which is always situated in a nexus of power. These dynamics have health-related outcomes. Racism has concrete consequences for human biology, which is socialized in historically specific contexts of culture, power, and political ecology (Goodman and Leatherman 1998). Historical archaeology is also unburying new layers of understanding about past landscapes of race and racism. Studies of the material cultural remnants of plantation slavery, maroons (runaways), free and freed communities, and the cultural life of other racialized or subracialized groups (e.g., Irish immigrants) fill in some of the gaps that historiographical research cannot (Orser 1998; Singleton 2006).

Other trends are studies of whiteness, which shift from the traditional focus on racial subordinates (Brodkin 1998; Buck 2001). Critical studies of race and racism are also examining indigeneity, especially in contexts in which the concept of ethnicity has provided the conventional analytical lens (Cowlishaw 1999; Wade 1997). Analyses of nontraditional Indians and African descendants with a history of contact with or even citizenship in Indian nations are disrupting conventional boundaries of classification and identity (Sturm 2002; Warren 2001). There are also studies of racism as a site of human rights violation and of antiracism’s place within the international context of human rights struggle (Banton 1996; Harrison 2005).

Finally, anthropologists have been vigilant in challenging the latest revival of biological determinism (e.g., Herrnstein and Murray 1994; Current Anthropology 1996) and in detecting the potential dangers of reifying race in the Human Genome Project. The intellectual and ideological heterogeneity of anthropology precludes a consensus. In light of this, it should be of no surprise that the bell curve thesis made sense to Vincent Sarich (1995) or that Glenn Custred coauthored Proposition 209, the 1996 California civil rights initiative that aimed to dismantle affirmative action. Race has figured prominently in anthropology’s history of ideas and public engagement. That relationship is likely to persist.

RACE AND ECONOMICS

Commentaries by political economists about the concepts of race and ethnicity and the implications of those categories for economic behavior and outcomes date back to the eighteenth century. Classical political economists generally maintained that all groups have comparable abilities to make rational economic decisions. Variations in observed outcomes among groups were explained in terms of history, luck, and incentives. Incentives and markets were seen as especially powerful forces capable of generating convergence in observed outcomes. In contrast, most postclassical economists believed that permanent and semipermanent group differences in desirable wealth-generating characteristics are primarily responsible for differences in levels of development.

Although the Irish were often a principal subject of discussion, the colonization of the Americas and the massive expansion of African enslavement ensured that attention would shift to Native Americans and blacks. Much of that discourse consisted of thinly veiled rationalizations for policies of discrimination, exploitation, and oppression through assertions that the victims were less than fully human. The expropriation of Native American land was justified by a “natural law” argument by which so-called civilized communities were divinely mandated to master and transform that environment.

EARLY THEORIES

Philosophers’ theories of Caucasian, Aryan, and Anglo-Saxon racial superiority provided a rubric for distinguishing between the civilized and the uncivilized. The philosopher David Hume (1711–1776) insisted, for example, on the universality of human nature in 1748, but by 1753 he had become a staunch proponent of racial hierarchies. Hume wrote, “I am apt to suspect the negroes and in general all the other species of men … to be naturally inferior to the whites. There never was a civilized nation of any other complexion than white, nor even any individual eminent either in action or speculation.” (Morton 2002, p. 3).

Such contrived claims about black inferiority served to justify enslavement. As was noted by Eric Williams, “Slavery in no way implied, in any scientific sense, the inferiority of the Negro” (Williams 1994, p. 29). Supporters of slavery predicted disastrous consequences if blacks were emancipated. The inaccuracy of those predications did not deter mid-nineteenth-century postclassical economists who were influenced by the writings of anthropologists from fully endorsing notions of differences among racial groups in the capacity to exercise economic rationality. Nonwhites and the Irish were characterized as “lower races,” and the category “Africanoid Celt” and an “Index of Nigrescence” were introduced in 1870 to measure how close the Irish were to blacks (Levy and Peart 2002).

DARWIN AND MARX

Charles Darwin’s 1859 book On the Origin of Species by Means of Natural Selection, or, The Preservation of Favoured Races in the Struggle for Life provided additional fuel for speculations about racial hierarchies, although Darwin and some of his supporters were dubious about the extent to which the dictum “survival of the fittest” could be applied appropriately to human beings. Alfred Russel Wallace, for example, insisted in 1864 that natural selection does not apply to humans because of ethical issues deriving from the phenomenon of human sympathy. However, prominent social Darwinists, including Herbert Spencer (1820–1903) and William Graham Sumner (1840–1910), argued that human progress depends on unbridled competition in all areas of economic life. As individuals sought to improve their circumstances, continuous movement toward the perfection of the human race inevitably would occur.

Karl Marx (1818–1883) was fascinated by Darwin’s work, although his views about race were more nuanced than those of most of his contemporaries. Although Marx and Friedrich Engels (1820–1895) envisioned the eventual disappearance of national and ethnic identities through the expansion of global capitalism, Marx recognized that in the interim a variety of social formations were sustainable and that economic progress “does not prevent the same economic basis … from displaying endless variations and gradations in its appearance, as the result of innumerable different empirical circumstances, natural conditions, racial relations, historical influences acting from outside, etc.” (Marx 1991 Capital, vol. 3, p. 927).

Marx’s sensitivity to issues of race and culture is evident in his discussion of Native American societies, in which he expressed special admiration for the Iroquois, highlighting their “sense of independence” and “personal dignity.” In addition, his writings are generally devoid of many of the prevailing stereotypes about non-Western traditional societies, including India and pre-Columbian Mexico (Anderson 2002). Nevertheless, the influence of Darwin is suggested by Marx’s comments about the dependency of barbaric and semibarbaric countries on civilized ones, indicating that he, like most thinkers of that period, failed to recognize white supremacy as an overarch-
ing global phenomenon (Robinson 1983). However, unlike most postclassical economists, Marx believed that differences in levels of social development among groups could be mediated through social interventions rather than reflecting a permanent pattern enshrined by innate genetically or culturally based variations in development potential. He argued that “all this crippling under existing social relations has arisen historically, and in the same way can be abolished again in the course of historical development” (Marx and Engels 1976, p. 425). That view resonated with those of classical political economists who insisted on the efficacy of incentives and markets to produce convergence in economic behavior and outcomes.

**Racial Hierarchies in Postclassical Economics**

Pseudoscientific notions of racial hierarchies can be found in the writings of several prominent postclassical economists, including William Stanley Jevons, Alfred Marshall, Arthur Pigou (1907), John R. Commons, and Irving Fisher (1930). In 1871 Jevons stated: “A man of lower race, a negro, for instance, enjoys possession less, and loathes labour more; his exertions, therefore, soon stop. A poor savage would be content to gather the almost gratuitous fruits of nature, if they were sufficient to give sustenance; it is only physical work which drives him to exertion” (Jevons 1871, p. 183). Those postclassical economists explored a variety of areas in which racial variations in economic rationality were hypothesized to exist, including labor supply, family size, consumption, and savings decisions. Marshall wrote about savage life ruled by custom and impulse in which there was no conception of future planning and rational economic decision-making and people were incapable of steady work. Individuals belonging to the “lower races” were deemed to be especially prone to the consumption of luxury goods and alcoholic beverages (Marshall 1891).

Large-scale migration from southern and eastern Europe to the United States beginning in the last decade of the nineteenth century led to the extension of notions of racial inferiority to those population groups. In 1907 Commons warned, for example, that the new immigrants were genetically inferior and would reduce the genetic quality of the nation. Various postclassical economists characterized those immigrants as “untaxed imports” and advocated eugenics policies to improve the genetic pool of the nation, including measures to encourage fertility among the “superior” genetic stock and reduce fertility among those with “inferior” natural abilities, including permanent segregation, sterilization, and selective restrictions on immigration (Levy and Peart 2002).

As described by William Darity, several researchers who were actively involved with the American Economic Association during its formative years subscribed to the view that African Americans eventually would face extinction as a result of a combination of genetic deficiencies and social maladjustment. Proponents of that view refused to discard the underlying assumptions of black inferiority even after demographic trends contradicted the predictions associated with the “Black Disappearance Hypothesis” (Darity 1994).

**Revival of the Classical View**

Beginning in the 1930s, the Chicago School played a pivotal role in reviving the classical tradition of treating individuals as possessing equal competence to engage in rational economic decision-making and reestablishing the critical role of incentives and markets in conditioning human behavior. Frank Knight’s 1931 critique of the presumed correlation between time preference and race in a 1931 review of Irving Fisher’s *Theory of Interest* was a major turning point.

George Stigler and Gary Becker also helped undermine postclassical views about racially distinct time preferences. Becker’s well-known “taste” or preference theory of discrimination has determined the contours of discussions about race for most contemporary neoclassical economists (Becker 1957). His analysis was conceived as a response to the failure of economists to examine the phenomenon of racial economic discrimination systematically. Two exceptions to the pattern of neglect of this topic noted by Becker include a 1952 study of black workers in southern industry by Donald Dewey and a 1955 analysis of occupational racial wage differentials by Morton Zeman. In Becker’s model social identities are treated as economically nonproductive individual characteristics that may, however, have significant economic consequences. A racial group thus can be treated simply as the aggregation of those individuals identified by a particular classifying parameter, allowing neoclassical economists to ignore the economic implications of individuals’ decisions for the intensity of group identification. The key theoretical conclusion flowing from Becker’s model is that the competitive forces of the market inevitably undermine the economic impact of racial prejudices, which are presumably irrational. However, the persistence of inequality in outcomes across groups has been documented, and this finding poses a formidable challenge to the efficacy of Becker’s model. Among others, Patrick Mason (1999) has suggested that racial discrimination may be consistent with the competitive process.

**Later Reconceptualizations**

Efforts to explain persistent racial differentials have generated two markedly different approaches to reconceptualizing the relationship between race and economic
outcomes. One approach reintroduces the postclassical notion of racial hierarchies. Monographs by George Gilder and Charles Murray in the early 1980s assert that differentials in economic outcomes between blacks and whites stem primarily from dysfunctional behaviors endemic to black culture, including willful refusal to adhere to the traditional American values of hard work, self-reliance, future orientation, thriftiness, a strong emphasis on education, and individualism. Economists such as Thomas Sowell and Walter Williams readily integrated aspects of this discourse into their writings in the 1980s, and subsequently the number of subscribers to those views increased significantly (Akerlof and Kranton 2000; Loury 2002). Although claims about black genetic inferiority that were prominent during the postclassical period have been resurrected, few economists have been willing to endorse those claims openly (Herrenstein and Murray 1994).

The second approach to reconceptualizing the ways in which race affects economic behavior and outcomes revives the classical tradition of focusing on the role of incentives and institutions in reducing disparities and is associated with the emergent subdiscipline of stratification economics. Stratification economists conceptualize race as a produced form of personal identity that is responsive to changes in incentives for altruistic versus antagonistic behavior in social interactions. Collective identity is deemed to have economic value even as there are also costs to identity formation. As a consequence, reductions in intergroup wealth differentials are a necessary but not sufficient condition for eroding traditional patterns of collective identification. This conclusion is consistent with Marx’s views on the value of culture and institutions. Stratification economists believe that racial disparities and racial discrimination are endemic features of the U.S. economy and social systems that are reproduced by a myriad of institutional practices that require transformation to produce outcomes characterized by sustainable reductions in racial differentials. Like Marx, stratification economists recognize that historical inertia is a powerful barrier to change, leading to caution in making predictions about short-term reductions in racial differentials.

Race and Education

Race and education becomes a social issue when educational opportunities are differentially available to members of diverse racial groups within a society.

Educational discrimination has a variety of effects that often lead to interracial conflict. Because education is a major means of social mobility, discrimination in this domain forces less-favored racial groups to occupy lower-status jobs and receive less income. Such results form a vital component in a wider system of racial oppression—as in the former apartheid policies of South Africa and state-mandated segregation in the U.S. South. But educational segregation by race also operates to limit the life chances of discriminated racial groups in nations without such formal systems of oppression, such as Brazil. And in countries where social class and race are highly intercorrelated, as throughout Latin America, racial segregation in schools results directly from intense patterns of residential segregation by class.

Racially segregated schools are the hallmark of racial discrimination in education. Separate schools allow for vastly fewer resources to be provided for the oppressed race. Indeed, racially separate schools are so central to systems of racial oppression that they are tenaciously maintained in the face of efforts to end them. The protracted and only partially successful efforts to end segregated schools in the United States provide a striking illustration.

Public schools did not emerge in the U.S. South until late in the nineteenth century, and these early schools were for whites only. Black schools came later, after formal state laws for racial segregation had been sanctioned in 1896 by the U.S. Supreme Court in <i>Plessy v. Ferguson</i>. Although the case involved segregated railroad seating, its decision establishing the formula of “separate but equal” was promptly applied by the white South to schools, which became extremely separate and unequal.

It was fifty-eight years before the High Court overturned <i>Plessy</i>. By 1950, in two graduate education cases, the meaning of “equal” went beyond mere parity in brick-and-mortar terms to include such intangibles as faculty reputation and general prestige. The decisions prepared the ground for <i>Brown v. Board of Education</i> four years later to hold separate facilities to be inherently unequal. But implementing this unpopular decision has proven difficult.

Critical to the acceptance of mandated social change that runs counter to dominant public opinion is the perception of inevitability. The responses of the white South to the varying firmness of the High Court's rulings illustrate the point. With an uncompromising, nine-to-zero decision in <i>Brown</i>, the Court in 1954 generated a strong sense of inevitability. But in 1955 the Supreme Court retreated in its implementation order to a vague “all deliberate speed” formula (<i>Brown II</i>). This formula returned the enforcement of desegregation back to southern federal district courts without guidelines. Only when this weak order undermined the sense of inevitability did southern politicians become uniformly defiant and pro-segregationist organizations gain momentum. Then the opposition believed <i>Brown</i> could be effectively opposed. <i>Brown II</i> is not solely responsible for the violent opposition that followed, but its vagueness contributed to the resistance by eroding the strong sense of inevitability that had prevailed.
Consequently, the region’s school desegregation did not take hold until the federal courts lost patience between 1968 and 1973 (Orfield and Eaton 1996). This brief period saw court orders achieve sweeping gains—especially in the recalcitrant South but also in the cities of the North and West. By the 1970s the South had more racial desegregation in its public schools than any other region. But this process ended abruptly in 1974 when the Supreme Court reversed direction. In *Milliken v. Bradley* the Court by five to four struck down a metropolitan solution ordered by a district court to remedy the intense racial segregation of Detroit’s public schools. What made this decision so regressive is that such remedies were the only means available to desegregate the public schools of many of the nation’s largest cities (Orfield and Eaton 1996; Pettigrew 1981). Moreover, segregation between city and suburban districts is now by far the major component today in metropolitan school segregation (Clotfelter 2004). Decisions of the High Court from 1974 into the twenty-first century continued this trend, and allowed racial segregation of the public schools to return not only in the South but also throughout much of the United States.

Thus, *Brown* was largely reversed without the High Court ever stating that it was overturning the famous decision. By 2000 black children were more likely to be attending majority-black schools than at any time since the 1960s; 70 percent went to predominantly black schools and 37 percent to schools with 90 percent or more black students. The greatest retrogression during the 1990s occurred in the South, the region that had previously witnessed the greatest gains (Orfield 2001). And Latino school children became more educationally segregated from white children than African American children (Orfield and Eaton 1996).

Supporting this retreat from desegregated schools, the sociologist James Coleman (1926–1995) claimed in a highly publicized speech that urban interracial schools were impossible to achieve because desegregation causes massive “white flight.” Desegregation led, he claimed, to whites fleeing to the suburbs and leaving minority concentrations in central city cores. This research had serious weaknesses, and its policy recommendations ignored metropolitan solutions (Pettigrew 1981).

The “white flight” thesis is far more complex than Coleman claimed (Pettigrew and Green 1976). Some whites did move from large cities when school desegregation began, but this movement was neither universal nor permanently damaging. Some cities without any school desegregation also experienced widespread white suburbanization. Other cities experienced little such movement at the time of desegregation. And where so-called “white flight” to the suburbs did occur, it constituted a “hastening up” process; within a few years the loss was what would have been expected without desegregation (Farley, Richards, and Wurdock 1980).

But does school desegregation improve the life chances of African Americans? From the 1970s to the 1990s, black high school completion rates rose sharply. Although less than half finished high school at midcentury, by 2000 the figure approached that of white Americans. During these same years, the mean difference between black and white achievement test scores steadily narrowed (Neisser 1998). White scores were improving, but blacks who entered school during the late 1960s showed especially strong gains—when extensive school desegregation began. Mean racial differences in achievement tests were not eliminated, but they began to close. However, these positive trends stalled and were even reversed by the late 1990s once the federal courts allowed resegregation. Yet these trends are only suggestive, because other factors were also influential—notably, rising black incomes and such effective national educational programs as Head Start.

More to the point, did school desegregation expand opportunities for African Americans in the long term? An array of sociological studies tracked the products of desegregated schools in later life to find answers (Pettigrew 2004). With social class controlled, black children from desegregated schools, when compared with black children from segregated schools, are later more likely:

1. to attend and finish majority-white colleges;
2. to work with white coworkers and have better jobs;
3. to live in interracial neighborhoods;
4. to have somewhat higher incomes;
5. to have more white friends and contacts and more positive attitudes toward whites.

Similarly, white products of desegregation have more positive attitudes toward blacks than comparable whites from segregated schools. In short, desegregated education prepares black and white Americans for an interracial world.

These positive lifetime effects of desegregation are not limited to test score gains—more important is the fact that desegregation enables African Americans to break through the monopoly that white Americans have traditionally had on informational flows and institutional access. Sociologists have identified several interrelated processes underlying this phenomenon (Pettigrew 2004). These processes mirror the harsh fact that life chances in America flow through white-dominated institutions.

Desegregation involves interracial contact. Intergroup contact is one of social psychology’s best-established theories. A comprehensive meta-analysis found that 95
percent of 714 independent samples with 250,000 subjects show that intergroup contact reduces prejudice (Pettigrew and Tropp 2006).

Desegregation teaches interracial interaction skills. Given the nation’s racist past, neither black nor white Americans are skilled in interracial interaction. The products of desegregated schools have the opportunity to learn these skills. Their anxiety about such interaction is reduced. This is highly useful for both blacks and whites, for it contributes to their willingness to enter biracial environments and their acceptance in these situations.

Desegregation erodes avoidance learning. After long facing discriminatory treatment, some black Americans learn to avoid whites. But this reaction has negative consequences. It closes off for ghetto dwellers the better opportunities that exist in the wider society. And, like all avoidance learning, it keeps one from knowing when the situation has changed. Desegregated schooling overcomes such avoidance.

Desegregated blacks gain access to formerly all-white social networks, such as those that share information about colleges and jobs. This process does not require personal friendships: Weak interpersonal ties are the most informative, because close friends are likely to possess the same information (Granovetter 1983). Interracial schools allow black students to gain access to these networks.

Thus, although it is not a popularly recognized fact, the racial desegregation of America’s public schools has led to positive outcomes. But the resegregation of the nation’s schools in the twenty-first century threatens to reverse these beneficial processes.

Although the racial scene in the United States has many unique features, social research in other nations suggests that similar intergroup processes operate in schools throughout the world. Additional research is needed, but the separation of groups in schools and other societal institutions, whether the groups are racial or not, appears to have comparably negative effects. Indeed, in some interracial nations such as Brazil, the deleterious effects of separate education may be even greater than in the United States. Educational differences between Brazilians of different skin colors explains much of the nation’s variation in racial occupational inequality and its racial gap in white-nonwhite mobility (Telles 2004).

In addition to thwarting beneficial intergroup contact, intergroup separation triggers a series of interlocking processes that make group conflict more likely. Negative stereotypes do not just persist but are magnified; distrust accumulates; and misperceptions and awkwardness typify the limited intergroup interaction that does take place. The powerful majority comes in time to believe that segregated housing, low-skilled jobs, and constrained educational opportunities are justified, even “appropriate,” for the minority. In short, racially segregated schools reproduce racial inequality. Intergroup schools have proven one of the needed antidotes for combating these negative processes—from Northern Ireland to South Africa.

**RACE AND POLITICAL SCIENCE**

Although controversies surrounding race have arisen in a variety of nations since at least the sixteenth century, it has only been since the mid-twentieth century that these
issues have generated serious attention in the discipline of political science. Beginning primarily in the aftermath of such watershed events as the civil rights movement in the United States, the rise of Fidel Castro in Cuba, and the demise of the apartheid system in South Africa, political scientists have slowly begun to focus on the impact of race in politics. In particular, scholars have examined issues such as the impact of racial group membership and racial attitudes on public opinion and voting behavior, partisanship, and political incorporation.

The literature on race and politics is perhaps most developed in the United States, where race plays a role in the level of support garnered by black candidates. There is little doubt that African Americans represent a small percentage of elected officials nationwide and that self-identified black candidates are rarely elected in majority-white political jurisdictions. It is not at all clear, however, that blacks fare poorly among white voters because of their race. Scholars have sought to get a better grasp on this question by relying upon experimental designs as a way of isolating the effects of candidate race. When white voters are randomly assigned to experimental conditions wherein otherwise identical candidates differ only in their racial background, some studies have found that black candidates are evaluated less favorably relative to white candidates.

Racial considerations do not just figure prominently in biracial contests. Some political scientists argue that the contemporary American party system is primarily based on racial cleavages. According to this view, after the 1964 presidential contest pitting racial liberal Lyndon Johnson (1908–1973) against racial conservative Barry Goldwater (1909–1998), voters began to view the political parties as primarily distinctive on matters of race. This view became solidified with the War on Poverty, which seemed to link black candidates are rarely elected in majority-white political jurisdictions. It is not at all clear, however, that blacks fare poorly among white voters because of their race. Scholars have sought to get a better grasp on this question by relying upon experimental designs as a way of isolating the effects of candidate race. When white voters are randomly assigned to experimental conditions wherein otherwise identical candidates differ only in their racial background, some studies have found that black candidates are evaluated less favorably relative to white candidates.

Regional differences have not only emerged from standard survey data but also using experimental methods. James Kuklinski, Michael Cobb, and Martin Gilens (1997), for example, developed an unobtrusive method for gauging racial attitudes. In short, they provide a nationally representative group of respondents with an opportunity to indicate how angry they are at a list of four items, one of which (the experimental condition) includes a specific reference to African Americans, as well as three topics not related to race. A randomly selected half of the sample is asked only about the three nonracial topics (the control condition), and all respondents are assured that no one will be able to determine which specific item makes them angry. However, because of random assignment, if levels of racial resentment are higher in the experimental condition relative to the control, then the differences can only be attributed to racial concerns. With this technique, Kuklinski and his colleagues show that white southerners are far more racially resentful toward blacks than their northern counterparts. This difference is also much greater than the results from traditional surveys.

Racial schisms and the influence of racial attitudes do not just occur in the United States. Although some scholars have argued that Latin America and the Spanish Caribbean are mostly free from the racial strife associated with the United States, more recent work has called this Latin American exceptionalism thesis into question. For example, Mark Sawyer, Yesilernis Peña, and Jim Sidanius (2004) fielded surveys in Cuba, the Dominican Republic, and Puerto Rico and found that respondents perceived racial hierarchies in their respective countries that were very similar to those in the United States. Whites were consistently perceived as having greater social status, followed by “mulattos” and finally blacks. Similarly, in follow-up work, Sawyer has found that Cubans who identify as white are much more likely than their darker-skinned counterparts to perceive other races as less intelligent and moral.

Another area where scholars are beginning to examine the impact of racial identity and attitudes on public
opinion is South Africa. This country has, of course, been wracked with racial divisions since its founding and has only been a multiracial democracy since 1994. James Gibson conducted the first systematic nationwide survey of attitudes on racial identity, national identity, and the Truth and Reconciliation Commission. His 2001 survey included a large number of whites, blacks, “colored,” and South Africans of Asian ancestry. Gibson finds that race relations in South Africa are far more complicated than many often assume, with considerable variation on public opinion within racial groups. Nevertheless, whites are far more likely to not identify with blacks than are blacks to reject identification with whites. On a more optimistic note, he finds that white South Africans who have greater contact with other races are also more likely to embrace the results from the Truth and Reconciliation Commission.

In the United States, the empirical study of the impact of racial attitudes on policy opinion can be traced to David Sears and Donald Kinder, and their subsequent development of the theory of symbolic racism (also sometimes referred to as modern racism or racial resentment). According to this theory, a new form of racial attitude emerged in the waning days of the civil rights movement. Support for the biological inferiority of African Americans was discredited, but antipathy directed at blacks remained a powerful force among whites. This anti-black affect would, in the aftermath of the urban riots in the late 1960s, merge with the widespread perception that blacks were making unfair demands on the system and not working hard enough to get ahead. According to Sears and Kinder, it is this new form of racism—which blends negative attitudes about blacks with the perception that they violate cherished values such as hard work—that accounts for white opposition to various policies designed to achieve racial equality.

The theory of symbolic racism has sparked a spirited and longstanding debate in the literature as to the manner and the extent to which racial attitudes influence whites’ policy preferences. None of the critics insist that racism is nonexistent, or that it has no influence on the policy preferences of white Americans. Instead, controversy has arisen with regard to the ambiguity in the conceptual definition and the measurement of the theory. These criticisms have on occasion hit their mark, as the symbolic racism theorists have modified their measures and sought to specify their model more carefully. Some of the more recent work in this literature has, however, generally supported the theory (see, for example, Sears and Henry 2003).

An emerging literature on the influence of race-based campaign communications also highlights the enduring linkage between race and politics. This work suggests that these communications can be effective, provided they do not rely on overtly racist messages. Specifically, Tali Mendelberg (2001) has shown that subtle racial cues, such as pairing pictures of African Americans with a standard conservative narrative condemning welfare, increased the role of racial considerations in candidate evaluations. Although this literature is both provocative and promising, scholars have yet to explore the frequency or impact of candidate appeals that invoke race explicitly but in a way that could not be interpreted as “racist.”

**RACE AND RACIAL MINORITIES**

Although most of the racial attitudes literature focuses on the United States and white attitudes about African Americans, an emerging literature has begun to examine the role that race-based political perceptions have on black public opinion. Much of this research can be traced back to the pioneering work of Patricia Gurin, Shirley Hatchett, and James Jackson’s 1989 book, *Hope and Independence*. These authors argued that black attitudes about prominent political figures, such as Jesse Jackson and Ronald Reagan (1911–2004), are influenced strongly by race-based perceptions of group solidarity and group consciousness. This work, and much of the literature inspired by it, finds that African Americans’ racial attitudes and policy preferences seem to be driven more by their in-group bias rather than out-group animus. Additionally, high levels of in-group identity appear to account for the unprecedented levels of black political unity.

Unlike the study of African American political behavior, there has been comparatively little attention devoted to other racial and ethnic minorities in the United States, such as Latinos, Asian Americans, and Native Americans. This has begun to change, however, as these groups have become an increasingly large share of the American population. Of these groups, the most attention has been devoted to Latino politics. One of the central questions in this emerging field is whether theoretical models designed to explain the broader electorate, or subgroups such as African Americans, can also be applied to Latinos (de la Garza 2004). This comparison with blacks is a common one since both groups are socially and economically disadvantaged relative to whites and both groups tend to support the Democratic Party. One question researchers have asked is: Are Latinos more likely to participate in politics when Latinos seek or have already achieved elective office in the local jurisdiction? This pattern holds for blacks, and some research finds similar effects among Latinos in California. It remains to be seen whether this applies elsewhere in the country. Another issue that arises frequently in this literature is whether Latinos should be treated as a single ethnic group or if national origin is the more salient identity. There is not yet a consensus on this question, although it is clear that Mexican Americans and Puerto
Ricans tend to have different partisan and political preferences compared to Cuban Americans.

With the 2000–2001 Pilot National Asian American Political Study (PNAAPS), scholars have taken their first steps toward understanding the political views of this rapidly growing demographic group. Relying on this groundbreaking dataset, The Politics of Asian Americans (Lien et al. 2004) provides a wealth of descriptive information on this diverse population. For example, it reports that most Asian Americans identify with their country of origin rather than with pan-ethnic labels. Additionally, more Asian Americans identify with the Democratic Party than with the Republicans, although about half do not identify with either major party. Although this work is largely descriptive, it represents an important first step in mapping the contours and variations present among this largely foreign-born population. At a minimum, it is clear from the PNAAPS that many of the political theories and hypotheses developed for the larger electorate must be modified when applied to Asian Americans.

Race and Psychology

RACE AND PSYCHOLOGY

Before the formal institutionalization of psychology in the nineteenth century, academics attributed psychological qualities to specific ethnic groups (such attributions can even be found in Aristotle’s writings). However, the systematic combination of psychological characteristics with race occurred in the eighteenth century when Carolus Linnaeus (1707–1778) linked varieties of humans (“races”) with psychological and social characteristics in his taxonomy. Johann Friedrich Blumenbach (1752–1840) advanced the concept of the Caucasian based on his idea that European culture originated in the Caucasus. The term Caucasian, still used in empirical psychological studies, has no scientific validity.

In the second half of the nineteenth century, some European scholars suggested that the Caucasian variety divided into two branches, identified as Semites and Aryans. Both were associated with different psychological characteristics and formed the theoretical basis for Hitler’s ideology. In the 1860s John Langdon H. Down (1829–1896) studied the structure and function of various organs in “idiots” and “imbeciles.” He observed a group of individuals that he characterized as having round faces, flattened skulls, extra folds of skin over their eyelids, protruding tongues, short limbs, and retardation of motor and mental abilities. Down classified this group on the basis of their resemblance to racial groups. He suggested that the physical features and behavioral attributes of these individuals represented typical Mongols—hence the term Mongolism for what is now called Down syndrome.

Pioneers of social psychology such as Gustave Le Bon (1841–1931) incorporated an ideology of race into their studies of intellectual ability, emotion, and volition. Le Bon understood races as physiologically and psychologically distinct entities that each possessed an immutable race soul. Paul Broca (1824–1880) was convinced that non-European races were inferior and used a variety of scientific studies to prove his preconceived conviction. Francis Galton (1822–1911) argued that Europeans were by nature more intelligent than “primitive races” and suggested the quantification of levels of racial intelligence. In the United States, pioneers of psychology such as
Granville Stanley Hall (1844–1924), the first president of the American Psychological Association (APA), argued that “lower races” were in a state of adolescence, a claim that provided a justification for segregation.

Empirical race psychology was prominent and influential during the first half of the twentieth century. Race psychologists used the accepted methods of the discipline and applied them to the empirical comparison of various groups. An early example is the research emerging from the Cambridge Torres Straits Expedition, which produced psychophysiological data on racial differences. Many race-psychological studies were used to demonstrate the inferiority of certain races and thus were part of the program of scientific racism. American race psychologists performed empirical studies on immigrants and were motivated by fears that the “national stock” was declining. They participated in empirically “evidencing” the inferiority of southern and eastern Europeans and African Americans.

Based on the results of the Army Mental Tests, administered to 1.75 million American recruits during World War I, it was concluded that there were inborn racial differences between whites and blacks, and among various European “races.” Psychological studies played a role in the Immigration Restriction Act of 1924, which imposed quotas on the allegedly less intelligent European nations. Leading American psychologists participated in race psychology, including two APA presidents: Robert M. Yerkes (1876–1956), who played a decisive role in the army testing, and Lewis Terman (1877–1956), who supported segregated education. Also popular in race psychology was the study of the mulatto hypothesis, which suggested that a greater proportion of white “blood” in a black person’s ancestry would lead to higher intelligence.

Most of the empirical studies on race carried out in North America and Europe during this period were unable to overcome prejudicial ideas. Research found differences and these differences were frequently interpreted in racist terms. These studies were also unable to challenge the cultural meaning of psychological instruments, concepts, theories, and methods. After World War II and the international recognition that racism was an integral component of the atrocities committed in the name of racial superiority in Europe and Asia, empirical race psychology, which could not overcome its racist connotations, declined significantly. However, contemporary studies on differences among races on intelligence tests continue a racist legacy when these differences are interpreted as representing essential racial divisions in mental life or when ideas of inferiority or superiority are invoked.

Social psychologists began, as early as the 1930s, to shift away from studying race differences to researching prejudice. Some racial studies took on a different perspective and were performed in the context of challenging racism, especially in the United States, where racial conflict, injustice, and discrimination were still endemic. Kenneth Clark (1914–1995) and Mamie Clark (1917–1983) performed a variety of studies in order to demonstrate the negative impact of prejudice, racism, and discrimination on African American identity. The best-known studies included a “doll test” that assessed whether African American children preferred to play with a brown or white doll and which color they considered nice. Many of the children preferred the white doll and considered it nice. The Clarks interpreted the results as showing that black children had low self-worth, an argument that played a role in court cases concerning desegregation and also in the 1954 Brown v. Board of Education of Topeka case, in which the U.S. Supreme Court judged segregation to be unconstitutional.

In the wake of the civil rights movement, Lyndon B. Johnson’s War on Poverty, and early educational compensatory programs such as Head Start, a dedicated and high-profile group of researchers personally and ideologically committed to a naturalistic concept of race emerged in Great Britain and North America. In 1969 Arthur Jensen published an article in the Harvard Educational Review that challenged the idea of the value of compensatory education. He also suggested that because intelligence had a heritable component, it seemed reasonable to hypothesize that genetic factors might play a role in producing racial differences in IQ. His argument was speculative but had an enormous impact on the field of psychology and on society in general.

From a methodological point of view it is important to understand that even if intelligence has a heritable component, mostly estimated through twin studies, this does not mean that differences between groups can be explained through heredity. For example, a heritability estimate of .50 for IQ means that 50 percent of the variability of IQ that one finds within a given population can be attributed to heredity. Hypothetically assume that a researcher finds a heritability of 55 percent in a “white group,” 50 percent in a “black sample,” and 45 percent in a sample that contains various ethnicities (heritability estimates do not have a single true value and change with environment). These results mean that 55 percent of the differences that can be found within the “white group,” 50 percent of the differences within the “black group,” and 45 percent of the differences within the “mixed group” can be attributed to heredity. They say nothing about the differences between the groups.

In 1994 Richard Herrnstein and Charles Murray suggested in their book The Bell Curve that genetic differences might be involved in producing racial differences in IQ. Again, they provided no evidence for this speculation. Beginning in the 1990s J. Philippe Rushton promoted his
ideas of a racial hierarchy. He presupposed the existence of three major races (Orientals, whites, and blacks) and has argued that there is a three-way pattern of differences in brain size, IQ, and behavior. For Rushton, whites and Asian developed larger brains and are more intelligent than blacks because giving food, providing shelter, making clothes, and raising children during long winters was more mentally demanding than accomplishing the same tasks in permanently warm climates. Rushton has not provided any genetic evidence for his interpretations that genes cause racial IQ differences.

The genetic speculations of contemporary race researchers in psychology take place in the context of anthropological and biological research that posits race as a sociohistorical and not a natural-biological category. Empirical differences are not interpreted as inborn and as reflecting a natural hierarchy, but as variations that must be understood as the product of cultural difference. Advancements in genetic analyses have shown that the variation within traditionally conceptualized races is much larger than between them. Instead of three or five races one should assume several thousand populations that are in the process of changing. Empirical studies that include race as a variable are now often motivated by the idea that a sociohistorical concept of “race” should be taken into account when making generalizations in psychology.

Social psychologists have provided alternative and more complex explanations for ethnic group differences than have traditional race psychologists. Experimental stereotype threat research conducted by Claude Steele (1997) is of particular significance. It is based on the empirically validated finding that the threat of being negatively stereotyped leads to underperformance in accordance with that stereotype. A negative stereotype is threatening when it provides an explanation for one’s actions or experiences, or aligns with one’s self-definition. For example, when a test is presented as assessing intellectual ability, black participants underperform in comparison to white participants. When the same test is presented as assessing problem solving unrelated to intellectual ability (and therefore unrelated to stereotypes about black intellectual ability) both groups achieve the same level of performance.

Effects of stereotypes can also be found in other areas. A study examining the stereotype that Asians perform well at numerical tasks has shown that Asian American women performed better than a control group on a mathematics test when ethnic identity was focused on, but worse when their gender identity was highlighted (Shih, Pittinsky, and Ambady 1999). In addition, social psychologists have studied attitudes associated with minority life that increase successful psychological functioning. Robert Sellers has investigated the meaning that African Americans attribute to race in their self-definitions (e.g., Sellers and Shelton 2003). He has developed a conceptual framework as well as instruments to provide a comprehensive assessment of African American racial identity. Instead of focusing on the negative impact of prejudice and discrimination, he has studied the protective role of identity. He has analyzed how African Americans are able to live normal lives in a context of discrimination. This has allowed him to provide a more precise picture of African American realities.

Other researchers have looked at interethnic interaction and its consequences from the standpoint of both minorities and majorities. Nicole Shelton, Jennifer Richeson, and Jessica Salvatore (2005) have demonstrated that the expectation of being the target of prejudice has complex implications for the dynamics of interethnic interaction. For example, the more ethnic minorities expected whites to be prejudiced, the more they had negative experiences during interethnic interactions. Yet, for whites, the more ethnic minorities expected them to be prejudiced, the more positive experiences they had during interethnic interactions. Richeson and Shelton (2003) have also examined the influence of interracial interaction on the cognitive functioning of members of a dominant racial group. Racial attitudes were predictive of impaired cognitive performance for individuals who participated in interracial interactions. This means that the activation of racist beliefs on the part of “whites” actually reduces their own cognitive functioning.

Despite the human genome project and advancements in human population genetics, ideological struggles over the concept of race continue. In the genome era, psychologists have been publishing increasingly on race and psychology. Although many psychologists suggest that the results from genomic research demonstrate that a biological concept of race is not tenable in psychology, others disagree. What is evident from the history of race psychology is that scientific methods are not sufficient to prevent bias, prejudice, and racism. In fact, empirical research has been used to support racism. Finally, it must be emphasized that much of race psychology has participated in epistemological violence—meaning that psychologists have produced and distributed interpretations, presented as knowledge, that have negatively shaped the life, health, and opportunities of minorities.

RACE AND RELIGION

Although both *race* and *religion* are enormously difficult to define, almost all human beings in almost all societies recognize, shape themselves, and are shaped by representations, influences, effects of the phenomena and dynamics to which each term generally refers. Bringing these two freighted and problematic terms together in critical analysis may force consideration of certain issues that may otherwise not be addressed at all, or at least not addressed in the manner befitting their complexity. Notwithstanding evidence of phenomena associated with both terms going back to the beginning of social ordering among human beings—for example, language and behaviors—the understandings, usages, and representations most often associated with both race and religion among contemporaries in the English-speaking world were determined by interests at the beginning of the modern era.

RELIGION AND MODERNITY

The modern and contemporary English term *religion* is taken from Middle English (*religion*), and the Latin of ancient Rome (*religio*; *piety*; *re-ligare*, “to tie,” “to bind back”). Although different connotations and uses of the term have developed over the centuries in different cultures and settings, the baseline assumption that has persisted in the English-speaking world has to do with different understandings about the operations, officers, ideologies, rhetorics, and symbolic objects facilitating orientation to—that is, communication with and reverence of—what is understood to be the supernatural, the Other. This supernatural or Other is a social-psychological projection that can be experienced as a form of transcendence or as a special aspect of inward presence.

Those human beings for whom a certain set of the operations, ideologies, rhetorics, and symbolic objects come to mean generally the same things, through whatever means, are thereby bound together into a type of society. This society may be large-scale and international, nationalistic, or local and on the fringes of the dominant host society. It may have its beginning as an alternate, oppositional, unpopular, and illicit society, but over a period of time, with growth, complexity of organization, and social power, it may develop into a dominant force such that its boundaries overlap with the boundaries and interests of the dominant society. The binding effect of that large-scale “society” inspired by or reflective of “religion” then comes to be represented in recognizable external forms—in canonical practices, structures, societies, offices, officers, ideologies, and operations. Such forms generally have fairly serious ramifications—social-cultural, political, economic—for the larger host societies; and they are what distinguish “religion” in strict terms from some of the ongoing experiences, practices, and sentiments of single individuals often understood and claimed to be comparable.

What has come to be called “religion,” then, can be considered ways of orienting individuals to certain types of societies. Given this general function, religion has some specific complex purposes and effects—that of binding persons into a new alternate society or order. It simultaneously and to different degrees and in different respects separates such bound persons from all or some other societies that do not recognize and respond to the same forms. It leads to a binding with larger-scale pressure and challenge for the purpose of institutionalizing the new society’s ideologies within or across a larger expanse of society or territory.

RACE AND MODERNITY

The origins of the modern and contemporary English term *race* are not at all clear. The term has multiple origins...
and valences from different cultural settings and discursive domains. It comes from Middle and Old English (rase(e)l) and (rae) and from Old Norse (ra), meaning “a running,” “rush,” “swift movement,” “attack.” These meanings may have had an Indo-European base (-eras), carrying the meaning “to flow,” “to move rapidly.” The term has for centuries if not millennia been used most basically to refer to particular types of athletic competition. From this specific usage the term has been widely borrowed and pressed into service to reflect a rather wide range of provocative meanings in domains far from the original. Uses have come to be more figurative in order to reference different types of competition and differentiation.

Included among such figurative uses is the poignant usage whereby different groups of human beings are differentiated, classified, and hierarchized. That at the onset of modernity the term race came to be accepted by almost everyone—from scientists and learned scholars of many types within and beyond the academy to politicians in their chambers to the haranguers on the streets—as a way to refer to and classify human beings was consequential. That the term came to be used to refer to and classify human beings not on the basis of their activities, accomplishments, or exploits but in terms of external physical features, especially color of skin, was decisive. This change facilitated a type of freezing of categories to the point that, notwithstanding more recent scientific (especially biological) and postmodernist arguments about the problematic, even nonexistence, of “race” (in strict physiological terms) as applied to human beings, many observers and critics would consider the contemporary world to be obsessed with it and many persons—especially “racial” and “ethnic” minorities—radically (over-) determined by it.

RELIGION AND RACE AND MODERNITY

No responsible critical grasp or engagement of “religion” and “race” in our times is possible without attention to the specifically modern-era determination of the concepts and phenomena associated with the terms. The modern-era understandings and uses begin with the European encounters—through the exploits of their commissioned merchants, military seamen, explorers, and missionaries—with other peoples in the lands mistakenly and unfortunately called “new.” Beginning in the fifteenth century these contacts challenged and inspired Europeans to name and conceptualize themselves in relationship to the newly “discovered” peoples and their lands. This naming and conceptualization led to a type of hierarchy of human classification that squared with and justified the eventual domination of many of the newly discovered peoples. Notwithstanding the emergence of modern nation-states and their nationalist ideologies and fierce competition, in this period of “discovery” Europeans began to think of themselves more consistently and collectively as “European” in culture and orientation over against the several newly discovered other worlds and their ways, and they began to think of themselves as “white” over against the others who were “black,” “red,” “yellow,” and “brown.” The recognition of the differences between European and North American “white Christian European” ways (in all their variety) and the ways of the others came to be exploited. This exploitation came to include a conceptualization of power on terms that determined some of the others as inferior, befitting the roles of natural perennial servants and slaves. The “discovery” of other peoples by Europeans made for Europeans the “race”-ing of all peoples compelling and strategic.

In such circumstances “religion” became along with “race” a marker of associations and identities shaped in relationship to modern imperial forces. Throughout the nineteenth century and into the early twentieth century, the critical study of the “science” of religion, the history of religions and comparative religions, was invented, and the concept of “world religions” evolved in conjunction with the first convocation of the World Parliament of Religions. These developments reflected the heightened awareness of the complexity of the world, its many different peoples, traditions, varied global developments, challenges, and crises, including the beginning of global wars and their resultant power reFORMations and arrangements. Religion increasingly came to be seen as one of the reflectors of social-cultural differences, with a presumed hierarchy that established the “world religions”—those religions built around literacy and sacred books—as the superior formations. Within this larger period and set of developments, there could be found alongside the large transnational boundaries and formations—for example, the “Christian” West, the “Islamic” Near East, the “Hinduism” of South Asia; and the “Buddhist” Far East—modern nationalist religious formations—for example, French Catholics, German Lutherans, and Chinese Buddhists.

In relationship to these large-scale global formations, one can further distinguish the religions of the formerly colonized, enslaved, and otherwise dominated, who were through various more or less violent means heavily misSionized—for example, African American Baptists and Methodists, East African Anglicans, Korean Presbyterians, Mexican Catholics, Brazilian Pentecostals, Nigerian Muslims, and so forth. As religion was used to integrate persons into and to hold together large social-political formations, it also provided minorities and the subaltern within the large-scale formations media and means by which to register resistance and criticism. The symbols, offices, officers, operations, and ideologies that constituted local traditions, on the one hand, and the “religions” of dominants, on the other, have in certain situations been
critically engaged by the subaltern as part of efforts to undermine the social-cultural and political-economic effects of dominance as well as to help restructure identity and reorient themselves to the world.

The historical and ongoing consequences of the imbrication of the two categories are at best mixed. The enslavement and disenfranchisement of black peoples in Europe and in the Americas, the Holocaust and pogroms against Jews in Europe, the violence of apartheid in South Africa, ethnic conflicts and wars among black Africans, hate crimes in the United States and Europe, denominational splits, the Israeli-Palestinian-Arab world conflicts, the genocidal crisis in Darfur—these are just a few examples of religion-inflected conflicts in the modern world. Yet not to be forgotten are the biblically inspired songs and artistry as well as insurrections of the slaves and the religious piety and formations of the soldiers of the civil rights movement, of the modern-day Palestinian movement, and of the Irish Republican Army. These examples suggest that the confusion of “religion” and “race” set forth at the beginning of modernity is likely to obtain with mixed consequences for the futures that can be imagined.

RACE MIXING

Shortly after Europeans first arrived in America in the mid-1600s to colonize the region that would become the United States, the issue of race mixing arose. The concept of race itself was then just emerging in its modern form, but European thinkers drawing from firsthand accounts of encounters with Native Americans and Africans began debating the meaning and scope of the physiological and cultural differences among people from different regions of the world. The conception that eventually won out understood racial difference to be real, intrinsic to individuals, and linked to hierarchies of status and capability.

In addition to the well-known case of Pocahontas, the Powhatan woman who entered into a formal European marriage in 1614 with an English settler and traveled to England before her untimely death, there are many documented instances of intermarriage and other sexual connections between Native Americans and European settlers. Although unions between Native American women and European men were more likely to be acknowledged and accepted, occasionally European women partnered with assimilated Native American men or joined Native American tribes. As time passed partnerships between Native American men and white women became less acceptable culturally, and by the late 1700s these types of partnering gave rise to a stock story that a variety of Native American tribes readily kidnapped and assimilated white women forcibly. (James Fenimore Cooper's 1826 novel The Last of the Mohicans provides an example of this type of narrative.) Still, even as late as the twentieth century, descendants of prominent families in southeastern states such as Virginia and Alabama related family stories of their descent from early male European settlers and “Indian princesses.”

Race mixing between Africans and Europeans in the colonial era was also initially a matter of debate and confusion rather than censure. Records dating back to the mid-1600s suggest that colonial officials struggled to sort out whether sexual relations between slaves and white indentured servants were legally problematic. By the late 1600s several colonies had begun to regulate against relationships between white women and slave men by rendering them as crimes, shifting the status of white women involved with black men to that of slaves rather than free or indentured persons or by fixing the status of children produced in such relationships as slaves. By the dawn of the 1700s the legal status of slavery had been more firmly fixed, and the descendants of slaves were understood by most people in the southern colonies to be slaves themselves, absent formal emancipation by their owners.

Despite the centrality of slavery and its increasing connection to blackness, European conceptualization of race mixing in the Caribbean and Latin American
colonies did not initially rest upon a rigid bifurcation between white and black. As early as the seventeenth century white Spaniards and their descendants living in Mexico developed the concept of casta, a classificatory scheme for race mixing that categorized individuals by descent. In addition to introducing the categories of “quadroon” and “octroon,” designating individuals with three white and one black grandparents and seven white and one black great-grandparents respectively, such schemes provided means of taxonomizing by name various degrees of native and black ancestry. These categories had real legal consequences for the status and rights of individuals placed in them—in but one example, the required amount of tribute paid to the Spanish Crown varied on the basis of one's racial classification, and that variance marked individuals as belonging to particular classes and holding particular statuses.

At this point the cultural and legal differences between relationships involving white men and black women versus black men and white women became more distinct. Although both types of relationships had the capacity to produce children, intimate connections between white women and black men gradually became perceived as more worthy of censure, based on culturally embedded beliefs about the threat of black masculinity and the need to protect white femininity. Interracial intimacy between slave women and white men became defined as undesirable and occasionally scandalous conduct on the part of the white men, but the legal system did not define it as a crime even if the relationship was overtly coercive or violent; the children born from such relationships were universally understood to be slaves. (Same-sex interracial intimacy was not formally recognized or regulated other than under the general rubric of same-sex sexual intimacy, which was often culturally and legally effaced when between women and punished as sodomy when between men.)

In the Revolutionary era in the United States, blacks experienced a brief taste of a more egalitarian ideology as several northern states abolished slavery or set it on a course for extinction after the freedom of the United States had been won. Some states experimented with extending the franchise to blacks and women as well. By the 1820s, however, this openness had dissipated completely as the franchise was withdrawn in state after state and southern pressures to protect and defend the institution of slavery increasingly led to harsh application of fugitive slave laws. Nonetheless, by the 1820s a substantial and growing mixed-race population was established in the United States. Descendants of blacks and whites were called mulattoes, although some scientists who studied race in the United States, the Caribbean, and Latin America persisted with intricate classification schemes for various combinations of black, native, and white ancestry. Mulattoes were at the time understood to be a distinct race but one more closely related to the African race than the white race. In some circles in the South, mulattoes were particularly prized as house servants or concubines.

At the same time, although some descendants of Native Americans and whites assimilated into white communities and gradually forgot their mixed-race heritage over the generations, some tribes actively embraced mixed-race individuals and defined them as wholly Indian. In some regions of the South small communities composed of the descendants of free blacks and Native Americans who had resisted removal began to establish themselves. The Seminole Indians of Florida, Georgia, and Alabama are an example. Eventually the United States became frustrated with the Seminoles’ refusal to cede their land and move west, and the government entered into a long and vicious war to remove them forcibly, which was won only through the U.S. Army’s betrayal and capture of the Seminoles’ leader under a false truce.

As sectional conflict worsened, understandings of race and racial difference shifted toward a harder line based in emerging scientific theories about the superiority of the white race and the inferiority of other races. As scientists began to argue for a rigid hierarchy of physical, emotional, and intellectual fitness among the races, they also began to warn of the dangers of race mixing. In the 1840s and 1850s Debow’s Review, a southern agricultural and social journal, began to publicize much of this work, including various versions of the theory that the mixed-race descendants of white and black parents were inferior. As scientific debates hardened racial categories and separated them more broadly, new theories emerged about the dangers of racial mixing.

This scientific anxiety reflected and reinforced social and cultural anxieties about race mixing, which became increasingly disfavored. Although some black men accused of engaging in intercourse with white women were able to avoid severe punishment even in the South, such connections increasingly were framed as rape. And although white men continued to have the legal authority to exercise sexual control over slave women, many southern states passed laws limiting white slave owners’ ability to free their slaves and give them substantial property, actions that white men occasionally took to benefit their enslaved sexual partners and children. By the time of the Civil War many southern states had adopted rules that allowed property to pass to enslaved individuals by will only if they were first freed and then sent out of the state or the country.

Anxieties about race mixing ran high among whites as slavery was abolished and the possibility for a new, more egalitarian, political order arose. Two Democratic newspaper editors sought to capitalize on these anxieties by
secretly publishing a pamphlet extolling the virtues and benefits of race mixing, coining the word *miscegenation* to refer to the practice; they sent copies of the pamphlet to prominent Republicans in the hopes that some would endorse it. Although the plot failed, the term quickly became part of the public lexicon, and despite an intense constitutional struggle in the early postbellum years, bans on interracial marriage were passed and upheld across the South. Through the remainder of the nineteenth century and into the twentieth century, these bans spread into the western states as well.

Bans on interracial intimacy took different forms. Some states, such as Alabama, broadly criminalized attempts at intermarriage, interracial adultery, and interracial fornication between blacks and whites as felonies, and the courts interpreted these bans to bar sexual relationships that paralleled legitimate same-race marital relationships. Other southern states such as Florida made intermarriage between blacks and whites a serious crime but left interracial fornication at the level of a misdemeanor offense. Western states often incorporated a bewildering array of racial groups in their injunctions against interracial intimacy between whites and people of color; Native Americans were prohibited from marrying whites in many states, but the western coastal states also barred marriages between whites and Asians, whites and Hawaiians, and whites and Filipinos.

Through the first three decades of the twentieth century, cultural and legal definitions of race increasingly moved toward eliminating the broad array of terms for mixed-race individuals in favor of a limited range of rigid categories. The category of mulatto gradually disappeared in favor of a strict separation between black and white, with those formerly considered to be mulattoes reclassified as black. Although communities of racially ambiguous individuals with Native American, white, and black ancestors persisted in southern rural areas, they increasingly had to operate under difficult conditions of fitting into the legal regime of segregation, which presupposed a black-white binary universe.

The bans on interracial marriage fell to judicial attack, first in California's 1948 state court ruling in *Perez v. Sharp* that such bans violated the Fourteenth Amendment and then nationally in 1967 when the U.S. Supreme Court decided in *Loving v. Virginia* that Virginia’s antimiscegenation statute was unconstitutional. In conjunction with this, however, state legislatures in the West had been removing bans in the 1950s; by the time *Loving* was announced, only the Old South retained statutory bans. Although further judicial action was necessary to enforce the rule of *Loving* in a few southern states, by 1970 the legal struggle was essentially over regarding marriage. Social acceptability of interracial relationships required more time, and even in the early twenty-first century marriages between blacks and whites comprise only a small percentage of marriages in the United States.

Controversy over race mixing arose again over proposals to add a mixed-race category to the 2000 census, which allowed individuals to select more than one race as an identifier. Nearly seven million Americans identified themselves as mixed race or multiracial.

**RACE RELATIONS**

The term *race relations* entered the sociological lexicon through Robert Ezra Park (1864–1944), who pioneered the study of race at the University of Chicago. Before becoming a professor in 1914 at the age of forty-nine, Park did a stint as a reporter and then worked for eight years as
publicist and ghostwriter for Booker T. Washington (1856–1915), the founder of Tuskegee Institute in Alabama, whose mission was to provide blacks with “industrial education.” Washington, of course, is famous as the apostle of self-help and racial accommodation. He was catapulted to national prominence in 1895 with his speech at the Atlanta Exposition exhorting blacks to forego politics and to pursue education and manual labor. His core assumption was that once blacks demonstrated that they were deserving of full rights of citizenship, better race relations would ensue. This raises the tantalizing question: To what extent was Park, as he entered the nascent field of sociology, the purveyor of ideological tenets associated with Washington’s uplift ideology?

Park was also heavily influenced by the evolutionary theories prevalent at the turn of the century when he studied social philosophy at Harvard and in Germany. Herbert Spencer (1820–1903), the English philosopher and political theorist, applied Charles Darwin’s (1809–1882) theory of evolution to the social order, arguing that history progressed through a series of stages from lower to higher levels of development. Park, in turn, applied Spencer’s theory to the domain of race, and expounded a theory that “in the relations of races there is a cycle of events which tends everywhere to repeat itself” (1950, p.150).

According to Park’s famous formulation, the race relations cycle has four distinct phases. It begins with contact when different races come together through migration or conquest. This leads to conflict as the rival groups compete for supremacy. During the third stage, accommodation, the weaker group resigns itself to its subordination, and a racial etiquette is established that maintains social distance between the races. The final stage of the race relations cycle is assimilation, which involves the gradual but inexorable absorption of the subordinate group into the dominant group, culturally and biologically. Thus, according to Park, new races are formed out of “the broken fragments” of different racial groups, and the race relations cycle provides the impetus of human evolution.

Park applied the race relations cycle both to people of color and to “the races” of Europe who were flocking to Chicago and other American cities at the time he wrote. Park’s race relations model had a sanguine political subtext: it rebuffed the nativist claim that the new immigrants were “unassimilable,” and provided reassurance that the intermingling of the peoples of the world was the stuff of human evolution. As Park wrote in Race and Culture: “Every society, every nation, and every civilization has been a kind of melting pot and has thus contributed to the intermingling of races by which new races and new cultures eventually emerge” (1950, p.192).

Park acknowledged that the race relations model did not proceed as rapidly or completely when it came to people of color. Even so, he clung to his evolutionary optimism that the assimilation process eventually would run its course, and like Washington, he emphasized the great progress that blacks had made during the half-century after slavery. Park also shared Spencer’s view that attempts to influence the flux of history were in vain. He was contemptuous of social reformers, and exhorted social scientists to observe an Olympian distance from the world of politics. Thus, Park’s race relations model gave theoretical exposition and scientific legitimacy to Booker T. Washington’s politics of accommodation. As Charles U. Smith and Lewis Killian observed, Park “constructed a theory of assimilation which paralleled Washington’s program in its major premises of accommodation and assimilation, realism and optimism” (1974, p. 200).

Park’s race relations model emerged as the reigning paradigm in the social sciences, both in the United States and Britain (Banton 1967; Rex 1983). The hallmark of this paradigm was to normalize and naturalize race and racial inequality, and to remove them from the political realm. Even black demands for full civil rights remained off the radar screen of mainstream social science. In a trenchant analysis of the social science literature on race, Stanford Lyman shows how leading sociological theorists from Park to Gunnar Myrdal (1898–1987) to Talcott Parsons (1902–1979) avoided the issue of civil rights. Instead, they advanced teleological models that projected racial improvement as part of an evolutionary process of societal change. “Since the time for teleological redemption is ever long,” Lyman writes sardonically, “blacks might consign their civil and equilitarian future to faith in the ultimate fulfillment of the inclusion cycle’s promise” (1993, p. 394). Lyman concludes with an indictment of the entire discipline: “Sociology, in this respect, has been part of the problem and not part of the solution” (1993, p. 397).

The race relations paradigm had enormous implications for praxis as well as for theory. Social scientists of all disciplinary stripes were cast into the role of managers of the troubled and fractured “relations” between the races (Steinberg 2001). The root cause of racial conflict was seen as prejudice: the distorted, derogatory, and often malicious beliefs that placed a stigma of inferiority onto blacks and led to their discriminatory treatment. Sociologists over many decades have charted historical trends in the prevalence and distribution of prejudiced beliefs. Other practitioners in “the race relations industry,” as it came to be called, engaged in projects of education and social work, designed to bridge the racial chasm and to forge better, more tolerant and harmonious “relations” between the races (Killian 1979; McKee 1993). According to critics, the fatal problem with this otherwise innocuous approach was that it elided those structures of oppression that enforced black subordination: Jim Crow
laws in the South, racial apartheid in jobs and housing in the North, and structured inequalities along racial lines that pervaded all major societal institutions.

Nor was criticism of the University of Chicago’s race relations model only a matter of hindsight. There were some contemporaneous critics, though they were mostly black or Marxist, and therefore could be easily marginalized. Throughout his long career as both scholar and activist, W. E. B. Du Bois (1868–1963) treated racism not as an individual anomaly but as a feature of major political and economic institutions. In 1909 Du Bois was a principal founder of the National Association for the Advancement of Colored People (NAACP), whose main purpose was to secure full rights of citizenship for blacks. Oliver Cox (1901–1974), another black Marxist, directly challenged Park’s “new orthodoxy” on race relations, arguing that Park’s “teleological approach has diverted him from an examination of specific causal events in the development of modern race antagonism” (1948, p. 476). For Cox, race prejudice was merely “the social-attitudinal concomitant of the racial-exploitative practice of a ruling class in a capitalist society” (1948, p. 476). That both Du Bois and Cox were beleaguered and ostracized within the sociological profession, and their work dismissed as “propaganda,” underscores the intellectual hegemony of the Chicago School of race relations (Deegan 2000, p. 284).

Just as the Chicago School studiously ignored power “from above,” it was oblivious to the possibility of revolt “from below.” All of this changed with the eruption of black insurgency, beginning with the Birmingham, Alabama, boycott in 1955 and culminating with the passage of landmark civil rights legislation in 1964 and 1965. The ensuing societal crisis threw into question the prevailing paradigm on race. A pivotal moment occurred at the 1963 Annual Meeting of the American Sociological Association when Everett Hughes (1897–1983), a student of Robert Park, delivered his presidential address in which he pondered the reasons that sociology had failed to anticipate the civil rights revolution (McKee 1993, p. 9). Here was a rare admission of intellectual failure and an unmistakable sign of paradigm crisis. Indeed, with the intensification of racial conflict beginning with the Watts revolt in Los Angeles in 1965 and the escalating black militancy during the 1970s, events demonstrated the utter failure of the race relations paradigm to shed light on the forces that were tearing American society apart. The time was ripe for paradigm change.

TOWARD A NEW PARADIGM

The civil rights revolution engendered a “scholarship of confrontation” that emphasized the centrality of race and racism, and incorporated minority and radical voices that had long been relegated to the fringes (Steinberg 1995). The most important revision to the race relations paradigm came from a book that was a collaboration between Stokely Carmichael (1941–1998), a frontline activist, and Charles V. Hamilton, a political scientist at Lincoln University. In Black Power (1967), Carmichael and Hamilton posited a distinction between “individual racism” and “institutional racism,” the latter referring to the ways in which racism is not necessarily predicated on racist motives but rather embedded in routine institutional practices that reproduce racial inequalities. The concept of institutionalized racism provided a crucial theoretical underpinning for affirmative action policy, which succeeded in integrating significant numbers of blacks into blue-collar industries, corporate management, and the professions (Collins 1983; Darity and Myers 1998).

In another landmark study, Racial Oppression in America (1972), Bob Blauner gave theoretical exposition to ideas that emanated from the anticolonial movements in the third world. Even his title, Racial Oppression, implicitly challenged the obfuscating terminology of the “race relations” model. Blauner also drew a sharp distinction between “immigrant” and “colonized” minorities—the latter referring to people of color who did not arrive as voluntary immigrants seeking a better life, but who entered American society en masse, as the result of conquest or slavery. These “colonized minorities” were not only exposed to more virulent prejudice, but were also denied the rights and opportunities that delivered immigrants from poverty.

Recent scholarship is marked by two opposing schools of thought. On the one hand, there has been a “scholarship of backlash” that contends that racism is of declining significance, and restores the victim-blaming discourses that antecedent the civil rights revolution (Wilson 1978; D’Souza 1995; Ternstrom and Ternstrom 1997). In the tradition of Washington and Park, these theorists see racial progress as contingent upon blacks acquiring the education and skills that explain the relative success of the black middle class. The flip side of this proposition is that the sources of persistent inequalities are located not in societal structures but in putative defects of black families, communities, and culture. Institutionalized racism is either ignored or defined out of existence.

On the other hand, there is a rival discourse that builds on “the scholarship of confrontation” associated with the civil rights movement, and posits “colorblind racism” as the central concept for both theory and praxis (Bonilla-Silva 2006; Brown et al. 2003; Feagin 2006). According to these writers, despite progress on some fronts, we are far from the colorblind society that Martin Luther King (1929–1968) envisioned in his 1963 “I Have a Dream” oration. Indeed, the claim of colorblindness has
been used as a smokescreen to conceal the retreat from the affirmative action and other antiracist policies that account for much of the success during the post–civil rights era.

This intellectual contestation is indicative of an ongoing struggle for intellectual hegemony between rival paradigms. The outcome may well determine whether sociology will continue to be part of the problem, as Stanford Lyman has alleged, or whether it will be part of the solution.

RACE RELATIONS CYCLE

Robert Ezra Park (1864–1944) was a member of the Chicago school of sociology and had a major hand in establishing the discipline of sociology in the United States. One of his many contributions was his “race rela-
The cycle can be illustrated in the history of black–white relations in the United States. The earliest period of competition and conflict in colonial days was followed by the institutionalization of slavery, an accommodation that began to emerge in the 1660s and ended in 1865 at the end of the American Civil War. After a brief period of renewed conflict (Reconstruction), black–white relations were stabilized in a second accommodation: de jure segregation, which ended in the 1960s. Since that time, black–white relations have returned to conflict and struggle. There are some signs of assimilation (e.g., rates of intermarriage are increasing, even though they remain a tiny percentage of all marriages), but continuing sharp distinctions in group identity and cultural traditions persist, reinforced by continuing racial exclusion and persistent racial inequalities of income and wealth.

While black–white relations have not (yet?) evolved to assimilation, examples of the completed cycle can be found in the histories of other American groups. European immigrants who arrived between the 1820s and 1920s competed for jobs, housing, and status and faced intense rejection, prejudice, and discrimination. Accommodations gradually emerged, and the descendents of the immigrants eventually assimilated and achieved parity with national norms in terms of occupations, income, and other measures of equality. Various researchers (e.g., Alba 1990; Gallagher 2001) have found that white ethnic identity is currently in its “twilight” and that descendants of European immigrants currently share identity, memories, and traditions with other white Americans.

Since the 1960s, the United States has received a second great wave of immigration. These immigrants are extremely diverse and compete for jobs and position in every niche of American society from high (e.g., scientists and surgeons) to low (e.g., day laborers and nannies), including work in the irregular economy (e.g., piecework in garment industry “sweatshops” and sex workers). Some analysts (e.g., Portes and Rumbaut, 2001) argue that some contemporary immigrant groups will not assimilate into the dominant culture but into the marginalized urban underclass, where they will learn cultures, values, and traditions that invert or challenge the dominant culture. Evidence for this assertion includes the high rates of unemployment and poverty and low levels of education for some groups, even those with substantially large third generations. For example, some recent immigrant groups, such as Mexicans and Haitians, bring low levels of education and job skills and take jobs marginal to the mainstream economy. In an era of hardening social mobility and increasing inequality, these immigrant groups and their descendents may find themselves permanently excluded from the mainstream job market.
Other analysts believe that this viewpoint amounts to little more than “blaming the victim” and present evidence (e.g., Bean and Stevens 2003) that suggests that the descendents of current immigrants will acquire the values and traditions of the larger society and, much like the descendents of the first mass immigration, gradually assimilate. For example, Alba et al. (2002) report that the tendency to speak English rather than the “mother tongue” at home increases by generation for recent immigrant groups. They found that the percentage of second-generation group members who reported that they spoke only English at home ranged from a low of 8 percent for Dominicans to a high of almost 80 percent for Filipinos. For the third generation, the percentage speaking only English at home rose for every group and ranged from a low of 50 percent for Dominicans to a high of almost 100 percent for Japanese and Filipinos. This pattern of language assimilation is quite consistent with the experiences of the descendents of the great wave of European immigrants who arrived between the 1820s and 1920s and may denote a movement of these groups toward higher levels of inclusion and assimilation. The ultimate fate of these groups—whether they will move toward assimilation or be caught up in a constant cycle of conflict and accommodation—will not be known for some time. As Park himself noted, immigration can be very fast but assimilation is by nature slow.

RACE RIOTS, UNITED STATES

Scholarly concern with riots and crowd behavior dates back to some of the earliest theorists who can be called social scientists. Gustave Le Bon (1841–1931), often credited as the most important early writer on crowd behavior, published The Crowd at the end of the nineteenth century, a book that influenced thinking about temporary assemblies of people for decades after. Le Bon and other important crowd theorists, such as Sigmund Freud (1856–1939), viewed crowds as crazed, criminal, unanimous masses of anonymous individuals who had ceded psychological control of themselves to the group mind and whose behavior was being directly controlled by the mob. Although this view of the crowd has been almost completely debunked in later empirical work, it is important not only because it had a decisive influence on the development of social psychology and sociology, but because the notion of mob psychology still lives on in the popular mind and the media. In particular, when serious rioting occurs, it is inevitable that commentators will draw on LeBonian notions to characterize both what happened and those who participated. But, in fact, riots in general, and race riots even more so, are expressive incidents in which actors have a large variety of motives for participating. They also make purposeful choices about their own behavior, and although some coordination of activity occurs, crowd members actually engage in very heterogeneous behaviors.

WHAT IS A RACE RIOT?

Defining race riots is a two-step process. First, we must come to an understanding of what constitutes a riot and then, among those events that qualify, decide which are fundamentally racial in character. One can easily imagine an event that would qualify as a race riot: hundreds of people in a pitched battle on the streets of a large city, where one racial group hurls rocks, bottles, and epithets at the other, and then receives an in-kind response. Such prototypical visions of race riots are straightforward. The edges of the concept, however, are more difficult to establish.

One tricky issue is the number of people involved. Rioting is undoubtedly a collective phenomenon—a single person cannot riot. But how many people are necessary before we can call the event a riot? Indeed social scientists have often faced this issue, and lacking a reason to use a particular threshold, have instead decided to call the events in question collective violence or civil disorders—and, in fact, many of the events analyzed in such studies would not be recognized as riots by most social scientists. Most social scientific studies of phenomena that are called riots appear to involve a minimum of thirty to fifty peo-
ple, even if the popular conception of a riot is something of a much grander scale.

A second defining characteristic of a riot is violence. Protest marches, confrontations between two racial groups, or even face-offs between citizens and police cannot be called riots unless some kind of physical violence transpires. Definitions of riots and of the broader category of collective violence almost always include the requirement that someone is injured or significant property damage occurs before the event can be counted. Sometimes, however, it is only necessary that such damage or injury be attempted, rather than accomplished. If a large crowd of protestors pelts the police with stones and refuse, but the police are adequately protected with riot gear so as to prevent any injury, scholars would still judge that a riot has occurred.

Third, riots must have a significant period of duration. A clash of only a few moments that is immediately broken up by authorities is rarely considered a riot. And finally, riots involve a temporary breaking away from the participants’ normal routines in a way that is not typically sanctioned by authorities or prevailing social norms. Rioting is not everyday behavior and also must be distinguished from sanctioned violence like an American football game or the running of the bulls in Pamplona, Spain.

Even having drawn a boundary about what social scientists have considered to be riots, it is still important to recognize the diversity within the category. Consider the differences among these subtypes of riots, all of which meet the demands of the core definition: sports celebration riots that often occur after championship games; genocidal ethnic purges such as those that occurred in Rwanda in the 1990s; food riots in Latin America; machine-breaking raids in nineteenth-century Britain; brawls among soccer fans throughout Europe in the 1980s and 1990s; lynch mobs in the southern United States in the late nineteenth and early twentieth century; immigrant protests of French police brutality that resulted in thousands of torched automobiles; and the urban riots of the 1960s that occurred throughout the United States.

Among these many forms of rioting, a race riot occurs when a racial grievance is expressed or is apparent through the behavior of the rioters. For example, if African American riot participants selectively loot white-owned stores, then a racial riot has occurred. If white Klansmen attack a peaceful African American civil rights rally, if an African American crowd burns down a government building in reaction to reports of white police brutality, or if Mexican Americans and African Americans clash on the border of their neighborhoods, causing deaths among one or both groups, then a racial riot has occurred. All of these scenarios were repeated throughout the 1960s in the United States.

WHAT CAUSES RACE RIOTS?

Although the U.S. urban riots of the 1960s dominate both the popular vision of race rioting and the scholarly literature on the subject, it is far from the only race rioting in the history of the United States. U.S. race riots can be thought of as belonging to one of two categories. The first are those typified by the Watts riot of 1965 (in Los Angeles, California); the Newark, New Jersey, riot of 1967; the Detroit, Michigan, riot of 1967; and the Washington, D.C., riot of 1968. These riots were most typically sparked by a confrontation between local police and African American residents of poor inner-city neighborhoods. In the most severe of these riots, the action lasted for several days and millions of dollars of property damage occurred before the authorities reasserted control of the riot areas. The activity of rioters was most often directed at damaging stores and government property, rather than attacking members of another racial group. Injuries and a few deaths did occur, but these were mainly the result of police attempts to contain and extinguish the riot. Imitative events followed in the wake of large riots and spread unrest across the region and the nation. And although there was a major concentration of these events throughout the 1960s, similar riots have since occurred in other countries.

Before the 1960s, the dominant kind of racial collective violence did not involve minority attacks on symbols of economic and political exploitation. Rather, they involved majority group members attacking minorities who had made gains in competition over occupational and residential turf. Here the dominant character of the conflict was white groups physically attacking members of minority groups, and destroying their property as well. For example, thousands of whites gathered in the “five points” area of downtown Atlanta in September of 1906 and ended up murdering dozens of blacks. Other such riots occurred throughout the United States, including both southern and northern cities. In the “Red Summer” of 1919, a devastating string of riots crossed the United States, killing many whites and blacks in cities such as Washington, D.C., Chicago, and Omaha. Although in extreme cases the authorities had to step in to quell the violence, more often than not, the attacks were carried out with the approval, if not the active participation, of the police.

For both of these types of race riots, economic conditions have been at the center of theorizing about their causes. In the case of the 1960s, sociologists hypothesized that unemployment and poverty were root causes of the dissatisfaction that African Americans seemed to be expressing through the riots. In this view, African Americans were not receiving their fair share of the American dream, and in many cases, they were struggling
to even survive. Lacking the political access to address their problems through institutional means, they turned to the streets in order to draw needed attention to their problems. Although this argument seemed more than plausible, the research has been considerably less than definitive. Studies attempting to explain why riots broke out in some cities but not others, and why riots in some locations were more severe than others, have had a hard time connecting rioting to poor economic conditions. Closely related ideas about insufficient social services, population changes, and political access to the city government have not been any more robust than the core economic indicators.

Competition notions, however, have had more success in predicting both kinds of rioting. Here, the idea is that competition over scarce resources (jobs and coveted residential areas) produce conflict—especially when one group begins to make gains perceived to be at the expense of another. The group that is losing ground is therefore motivated to fight back and to punish those who seem to be threatening its position. In the end though, economic conditions are not strong predictors of racial rioting. Economic hardship may very well be a prerequisite for rioting, but it is not sufficient to ignite the flames of rioting itself. Other conditions, such as poor relations between the police and the community, must provide a catalyst in areas where economic conditions have created fertile ground for unrest.

**RACE-BLIND POLICIES**

In a race-blind (or synonymously color-blind) society, persons of all ethnic backgrounds are supposedly viewed as equal and have access to the entitlements of a meritocracy. It is a theoretical position that gradually emerged in the post-1960s civil rights era and has become a contentious topic in both academic and social policy circles. Many advocates of race-blind policies, but not all, tend to be from the conservative-right school of thought. They adhere to the view that “racelessness” will help bring about equal opportunity for all and is ultimately good for society. Moreover, they view overt racism as an issue from the past that does not figure in the imagination of the majority of Americans. Hence, there is no longer a need for affirmative action policies (or positive discrimination) that were designed socially to engineer greater equality for minority cultural groups—in the United States, primarily African Americans, American Indians, and Hispanics—that had historically been underrepresented in key institutions such as education, law, the media, and politics. However, one could argue that any group considered as a “people of color” could come under an affirmative action mandate.

Race should not be viewed as the only criterion for affirmative action policies. The main beneficiaries of such policy initiatives have been white women. However, race is arguably the key factor in determining the push for race-blind policies. Those who are most vociferous in advocating race-blind policies tend to focus on race being the salient factor in creating what is often deemed reverse discrimination. Arguably, one of the key personalities in race-blind policies is Ward Connerly, who made his name after being appointed to the University of California Board of Regents by Republican governor Pete Wilson in 1993. Connerly is largely acknowledged as responsible for Proposition 209, which outlawed racial preferences in the California university system in November 1996. Ironically, Connerly professes to be of one-fourth African ancestry, and his opposition to racial preferences in admission to universities or to employment, which gained widespread support in the 1990s, shows no sign of diminishing in the 2000s. Indeed, writers of all hues such as Shelby Steele, Ann Coulter, David Horowitz, Dinesh D’Souza, and Thomas Sowell, to name a few, have provided ideological support for Connerly’s position as probably the preeminent anti-affirmative action proponent.

Interestingly, some conservatives employ Dr. Martin Luther King Jr.’s perspective on race to argue for race-blind policies, arguing that King wanted his children to be judged by the content of their character and not by the color of their skin. However, it could be contended that race-blind advocates have taken King’s perspective out of context. It would be wrong to suggest, for example, that he envisioned a society devoid of color or that his children would not be seen as African American. Rather, he wanted a society that did not discriminate on the grounds of race, as had been the case for centuries through the African American experience of enslavement, segregation, and sec-

Race-Conscious Policies

Race-conscious policies are usually defined as those explicitly and directly intended to affect the life conditions of racial minorities, whether it be to promote racial equality or preserve the racial status quo. Race-conscious policies in the contemporary United States have been targeted predominantly at African Americans.

Race has been entangled with public policy throughout the history of European settlement in North America. Slavery was introduced early in the seventeenth century, and lasted until the Civil War (1861–1865), more than two centuries later. It was soon replaced by the two-caste racial system known as “Jim Crow,” which was most formally organized in the American South. That system was passionately supported by most southern whites, and it

Race-Conscious Policies

was, by common agreement, essentially ignored in both local and national political debates for many years.

The 1930s brought renewed political attention to race. The peremptory lynching of blacks for real or imagined offenses was then a common, though extreme, technique for enforcing the two-caste racial system. Federal anti-lynching legislation was proposed in Congress, but President Roosevelt refused to support it, fearing the loss of his critical political base in the white South. Roosevelt’s centerpiece economic legislation, however, which created the Social Security system, was intended to provide support to all older and disabled Americans, regardless of race. But at the behest of white congressmen from the South, agricultural workers and domestic servants were excluded from coverage, leaving those predominantly black segments of the southern work force dependent on the low wages normally paid by white farmers, businessmen, and families. Race was central to congressional debates on both of these issues. Unlike lynching, however, social security was not an explicitly race-conscious issue.

At the end of World War II (1939–1945), formal racial segregation and discrimination remained the cornerstones of southern society, and they were only somewhat less common elsewhere. Civil rights advocates soon began to propose a wide variety of race-conscious policies, all designed to eliminate the elaborate machinery of law, institutional practice, personal behavior, and public opinion that sustained racial inequality. These proposals were almost always greeted with overwhelming opposition in the white South, and they were often initially opposed by whites elsewhere as well. Nevertheless, a number of civil rights successes followed, including the 1950 desegregation of the armed services; the 1954 Supreme Court order to end school segregation; the Civil Rights Act of 1964, which mandated the desegregation of public schools and public accommodations and banned discrimination in employment; the Voting Rights Act of 1965, which outlawed discrimination in the voting process; the 1967 Supreme Court order invalidating laws against racial intermarriage; and the Civil Rights Act of 1968, which banned discrimination in housing. By the 1970s, these paradigmatic race-conscious policies had largely eliminated both the legal foundations and public support for formalized racial segregation and discrimination.

Still, major racial gaps persisted in most areas of life, including educational attainment, income, wealth, health, crime, and mortality. These racial gaps were national problems, but outside of the South they often were perpetuated by custom rather than law, making them more difficult to address directly. Moreover, many of the new civil rights policies had initially been accompanied by weak enforcement provisions. For example, the 1964 Civil Rights Act mandated equal opportunity for all individuals, but lawmakers explicitly rejected proposals that would have required racial equality in outcomes, such as quotas for hiring or college admissions.

In the 1970s, a variety of new race-conscious policies were proposed that were more results-oriented. That is, they were designed to produce actual racial equality in outcomes, not just opportunities, with less concern about the reasons for inequality. The end of de jure segregation, originally created by the legally mandated separation of the races in the public schools, had not ended extensive de facto segregation, created by the largely voluntary residential separation of the races. In 1971 the Supreme Court first ordered the use of busing to redistribute children across school systems. Court-ordered busing soon spread throughout the nation as a solution to racial segregation. This race-conscious policy was vastly unpopular among whites, and racial prejudice was apparently the strongest factor in generating that white opposition.

“Affirmative action” became a blanket term applied to results-oriented policies in several domains, including preferences for minorities in hiring and promotion, “set-asides” of government contracts for minorities, and preferences for underrepresented minorities in higher education. Such policies soon attracted opposition from many, if not most, whites, again often driven by racial prejudice. A series of closely divided court cases followed. The Supreme Court narrowly upheld preferences in higher education in the 1978 Bakke case, but in 2003 it rejected one University of Michigan plan while narrowly accepting another.

A second category of race-conscious policies is somewhat different. Like de jure segregation, explicit racial policies directly target blacks. Like de facto segregation, implicit racial policies may disproportionately affect blacks, although they are designed to be universalistic and apply equally to people of all races. Implicit racial policies are marked by advocacy that usually includes racial overtones in its visual aids and stereotyped anecdotes, by the polarization of the attitudes of whites and blacks (both among advocates and the mass public), and by the role of racial attitudes in motivating policy preferences, both pro and con.

“Welfare” is a prominent implicit racial-policy domain. In the late 1960s, “the poor” came to be increasingly identified by many Americans as being urban and African American (Gilens 1999), and the opposition to “welfare” among whites became rooted more strongly in racial animosity. A second implicit racial domain is that of “law and order.” A number of tough crime policies have been tainted by their association with racial inequality, such as the death penalty, “three strikes” laws, mandatory sentencing laws, the opposition to “permissive” judges, and the especially harsh penalties for the sale and use of
crack cocaine, which is used extensively by African Americans. A celebrated political case focused on Willie Horton, a black murderer who, while on a weekend furlough from prison, brutally assaulted a white couple in their home. This case was used successfully by the 1988 Republican presidential campaign to attract racially conservative whites.

A third category of potentially race-conscious policies has been generated by the expanding waves of immigration to the United States and western Europe. Immigration policies concerning border control, citizenship requirements, and public services for the undocumented are all relevant here, as are language policies, such as bilingual education, multi-language ballots, and the drive for an “official” language. These political issues do not comfortably fit within the category of explicit race-conscious issues, because most of the new immigration to the United States has come from Latin America and Asia, rather than involving people of African descent. However, they often are framed as explicitly targeting other stigmatized groups, such as Mexican Americans.

By the turn of the twenty-first century, white support for the old system of legalized segregation and discrimination had virtually disappeared. However, there was still much white opposition to policies intended to remedy racial inequality, and new theories explaining this opposition began to develop. Social psychologists described new forms of racism—such as “symbolic racism”—that had replaced the old, discredited Jim Crow racism (Sears & Henry 2005). Sociologists, meanwhile, focused more on whites’ feelings that black gains threatened their real resources and superior group position (Bobo and Tuan 2006).

The gradual movement of American society to formal racial equality and the expanding numbers of non-European immigrants have converged to produce new political debates on multiculturalism and identity politics. “Multiculturalism” has several meanings, variously describing a society with peoples of many cultures, tolerance and equal treatment for people differing in values and customs, or the privileging of group identities as bases for resource allocation, political alliances, and even self-concepts (Citrin et al. 2001). Although multiculturalism has been influenced by the long intellectual history of black nationalism, it has spread far beyond race and ethnicity as group categories, and therefore well beyond race-conscious policies as well.

RACIAL CLASSIFICATION

Modern racial classification schemes emerged in the eighteenth century during a period of European colonization and empire building. Racial classifications have been central to state formation, nation building, and the establishment of hierarchies that determine access to power in the form of material, social, cultural, and natural resources. The racial classifications schemes employed in the English-speaking, French-speaking, Spanish-speaking, and Portuguese-speaking worlds were established during European colonialism, when indigenous peoples were conquered, enslaved, and forcefully incorporated into European nation-states as colonial subjects. These classification schemes are not simple reflections of “biological” or natural differences in physical appearance, but power relations that were established during the seventeenth and eighteenth centuries as colonial expansion brought people in diverse regions under the control of Europeans.

HISTORICAL BACKGROUND

The scientists who produced classifications of human groups were Europeans. Carolus Linnaeus (1707–1778), a Swedish botanist, produced the first modern classification of human populations in 1735. Linnaeus, the founder of
scientific taxonomy, divided the genus *Homo* into four racial types: Eurapaeus, Americanus, Asiaticus, and Africanus. During this period the dominant view was monogenesis—the view that all humans were the descendants of a common original ancestor. Johann Blumenbach (1752–1840), a German professor of medicine, became the most influential of the scientists who classified human populations. Between 1770 and 1781 Blumenbach proposed the division of humans into four and later five “varieties” that represented the world’s major regions: Caucasian, Mongolian, Ethiopian, American, and Malay. Blumenbach considered women from the Caucasus region in Russia to be the most beautiful of all Europeans, so he chose them to represent the European ideal type, and all other human groups were a departure and degeneration from this ideal. These racial typologies were ranked and were not considered equal in aesthetic beauty, intelligence, temperament, or morality. The racial typologies created by Blumenbach reflected a belief in European supremacy, legitimated racialized slavery, and the subordination of groups of people based upon their physical and cultural differences. These racial classification schemes linked physical traits such as eye color, skin color, hair texture, nose shape, and mouth size to intellectual capacities, cultural traits, and moral temperaments. To formulate these classification schemes Blumenbach and other scientists relied primarily on the written observations and descriptions of “ordinary” men who earned their living as slave traders, slave owners, merchants, or others in dominant positions over peoples whom they considered “savages.”

By the end of the eighteenth century the economic interests and political goals of European colonizers had firmly established racial classification systems as tools employed by nation-states to subordinate the people whom they had colonized and conquered. Three hundred years after the establishment of modern racial classification systems, patterns of social and economic inequalities remain between racial and ethnic groups in multiracial nations throughout the world. The racial typologies established by European men during the eighteenth century are used as “legal” and political identities, and they continue to inform “scientific” thinking today. Many of these typologies’ terms remain in use today. For example, the term *Caucasian* continues to be used as a reference to white people of known and visible European ancestry, and is a term of self-identification in North America. In some countries such as the United States it is common to classify children by race when they are born in hospitals. Race, like gender, has become part of people’s “legal” identities, which follows them through their lives as they move from various institutions such as schools, hospitals, and prisons. Their “racial” and ethnic identity may change as they move across nation-state boundaries where the criteria for inclusion or exclusion in a racial category changes. In other cases, individuals may be “reclassified” as adults upon their request. For example, prior to the dismantling of apartheid in South Africa, special legal courts were established to handle racial reclassification cases.

**POLITICS OF RACIAL CLASSIFICATION**

In nations that were structured by state-sponsored racial segregation (and white supremacy) such as the United States and South Africa, one’s racial classification determined where one could live, purchase a home, and attend school, whom one could marry, and what occupation was suitable. In other words, all aspects of one’s economic, intimate, social, and political life were structured along racial lines. In the late twentieth century as state-sanctioned racial inequality such as Jim Crow segregation in the United States and apartheid in South Africa were dismantled, nations established a range of public policies designed to remedy past group-based discrimination. These policies have taken various forms, such as affirmative action in the United States and positive discrimination in the United Kingdom. Although nation-states have dismantled *de jure* (legal) racial segregation and formally criminalized discrimination against members of racial and ethnic minorities, one’s racial status continues to overdetermine an individual’s life chances and access to resources in multiracial societies.

Social scientists have documented patterns of social inequality that demonstrate that belonging to a racially dominant or racially subordinate group is correlated with infant mortality rates, educational achievements, access to healthcare, housing, and wealth, and freedom from routinized violence. In other words, resources and privileges are unequally distributed along racial and ethnic lines. Public-policy initiatives by nation-states and local governments depend on racial classifications to remedy and counter group-based inequalities. Governments employ census data that classifies individuals by race and “ethnicity” in order to redistribute resources such as education, health care, housing, public assistance, and other resources in an effort to eliminate and minimize racialized inequality that continue to determine life chances. For example, in the United States, the direct descendants of American Indians and the descendants of enslaved Africans are more likely to endure intense poverty, lower life expectancies, residential segregation, social isolation, higher suicide rates, and higher infant mortality rates, and are more likely to be victims of hate crimes when compared to European and Asian Americans in the same age cohort and/or class position. One’s racial classification is strongly associated with one’s location in economically impoverished regions and communities where access to valued resources is minimal.
CHANGES IN THE U.S. CENSUS CATEGORIES
Racial classification schemes reflect power relations and political constituencies and thus are not stable. For example, in the United States, racial categories have been added, removed, revised, and altered during the past 300 years in response to demographic changes, immigration, political mobilization, technologies, cultural shifts, and economic interests. The United States is unique in its historical enforcement of what has become known as the “one-drop rule,” in which a person of multiracial ancestry, who had known or visible African ancestry, is legally classified as “black,” regardless of appearance, cultural training, and self-identification. The one-drop rule has been consistently upheld by state and federal courts. In states such as Louisiana there were so many people of African ancestry socially classified and living as “whites” that “race clerks” were hired to strictly enforce the one-drop rule. A number of significant changes have occurred in the census during the past 100 years including changes in census categories, instructions to the census enumerator, and the ability of individuals to self-report their race and ancestry.

In 1918, the U.S. Census Bureau estimated at least three-fourths of all native blacks were racially mixed, and it predicted that pure blacks would disappear (see Davis 1991, p. 57). Consequently after 1920 the mulatto category was removed from the census and no further attempt was made by the U.S. government to systematically count the number of visible mulattos in the United States, partly because there were so many persons with some black ancestry who appeared white.

Social scientists have documented the inconsistencies in the logic employed by the U.S. census and the disparity between social-cultural and scientific definitions of race. By 1960 the practice of self-identification by race replaced the earlier practice in which the census taker assigned race. Beginning in 1960 the head of household indicated the “race” of all of its members. Surprisingly this did not introduce any noticeable changes in the numbers of blacks in the population. In 1970 the Hispanic category was added to the U.S. census for the first time. While in 1980, for the first time, a question on ancestry was included in the census. In response to increased political mobilization by members of interracial or multiracial families, the United States added the category “multiracial” to the 2000 census. In the following year the United Kingdom also added a “mixed race” category to their 2001 census. These changes in the official census reflect political struggles over the boundaries between and within racial groups, as well as how resources will be distributed and who will be counted and included in racial and ethnic minority categories. Racial classification schemes are socially produced, yet they have real material, social, and economic consequences for members of racialized groups.

RACIAL SLURS

Racial slurs, often called racial epithets, are words or phrases that refer to members of racial and ethnic groups in a derogatory manner. Slurs and all other forms of racial defamation dehumanize targeted groups and justify racial oppression by suggesting that targeted populations are unworthy of equality (Clark 1995, p. 6). Racial slurs take myriad forms and are often adapted by users to fit a variety of contexts. They may mention a racial category explicitly (e.g., "Japs" for Japanese people, "Chinks" for Chinese people, and "spics" for Hispanics) or indirectly allude to the targeted racial group by referencing common derogatory stereotypes (e.g., "porch monkeys" and "spearheaders" for African Americans). Other racial slurs refer to historical encounters (e.g., "redskins" for Native Americans). In some cases, racial epithets targeting one group are derived from slurs targeting a different group (e.g., "sand niggers" for Middle Eastern people). Other examples of racial slurs commonly used in the United States include nigger, wetback, coolie, kike, and dago.

Racial slurs are usually created and used primarily by the dominant racial group in society. A variety of sociopolitical circumstances govern the creation and duration of racial slurs. Initial contact between racial groups in the form of militaristic exploration (colonialism) or migration frequently leads to racial conflict. This, in turn, often generates racial imaging and racial slurs, when one racial group considers itself distinct from and better than another. During conquests, European conquistadors and colonists invented numerous racial slurs (for example, "Indian savages") to denigrate and rationalize the oppression of Native Americans. Subsequent generations of European Americans coined other slurs to disparage and rationalize the subordination of African Americans and various populations of immigrants of color.

After their creation during initial contact, racial slurs persist in two contexts, which Leslie Picca and Joe Feagin (2007) have termed the social frontstage and backstage. Frontstage refers to multiracial environments where racist acts are performed. These environments range from relatively private gatherings to major public events. Members of dominant groups use racial slurs in public spaces to intimidate members of other groups and to prevent challenges to the dominant group’s status and privileges. Racial slurs are extremely common when the economic and political privileges of dominant groups are threatened by resistance from oppressed groups. In 1994 six African American employees were embattled in a racial discrimination lawsuit against the Texaco company. Threatened by their act of resistance, some angry Texaco executives were tape-recorded referring to the employees as “black jellybeans.”

Explicit public uses of racial slurs range from their appearance on signs during white supremacist demonstrations to their use by whites during lynchings and other incidents of racial violence. In the absence of a sufficiently powerful formal or informal social structure, dominant groups may use racial slurs as the primary colloquial term for discussing racial others. In contemporary times, some have resorted to referring to African Americans with derogatory “coded” racial slurs. In 2006 the Equal Employment Opportunity Commission filed a lawsuit against a medical clinic that was referring to a black employee as a “reggin,” the N-word spelled backwards. There has been a rise in the use of “coded” racial slurs such as “boy,” “drug dealer,” “you people,” and “thug.” These coded racial slurs carry a contemporary message of hate.

Despite the attention such public usage receives, racial slurs are now most commonly used backstage, in settings where only members of the dominant racial group are present. In this environment, slurs insult the relevant racial others and build solidarity among those present. Formal and informal sanctions against the public use of racial slurs have created a climate of political correctness in which most people refrain from the use of terms and symbols that may be viewed by other populations as offensive. Ever since the moral climate of the civil rights movement there have been changes in the United States that have curbed the public use of racist epithets; however, in private, members of the dominant racial group may continue to use them with impunity.

Because race is a social construction and not a biological reality, over time a minority group may be redefined as part of the dominant racial group. As this process occurs, these redefined groups are less often the targets of racial slurs. For example, in the United States, white Anglo-Saxon Protestant Americans originally classified Irish Catholic immigrants as nonwhite and racially inferior. During the mid-nineteenth century, established European Americans targeted the Irish with racialized slurs, such as "paddy" and "mick." As generations of Irish Catholic families assimilated to the Anglo-Saxon core culture, the established white groups were unable to distinguish Irish people from other European Americans, and the use of anti-Irish slurs decreased. The use of slurs against racial groups who cannot pass as white does not decline as sharply, regardless of their degree of cultural assimilation.

Arguably, no racial slur has been as prominent and damaging as nigger, which remains a potent epithet used against people of African descent. Use of nigger is so hurtful to African Americans that most people publicly reference it as “the N-word.” Possibly derived from niger, the Latin word meaning black, nigger has been decidedly derogatory since the eighteenth century. The term has pri-
Racial Slurs

...marily been used by white Americans to derogate blacks as unworthy of equality due to their alleged intellectual, moral, and cultural inferiority. Although generations of white Americans used nigger as their primary term for referring to African Americans, whites would often use the slur during explicitly violent racist actions, such as lynchings, adding an implicit threat of violence to any use of the word. Despite contemporary use in popular media, sometimes by black musicians attempting to defang its potency, nigger retains its power to insult, intimidate, and threaten African Americans.

In the United States, many citizens have looked to the political and judicial systems for relief from hateful terms. In a landmark case, Chaplinsky v. New Hampshire (1942), the U.S. Supreme Court ruled that "fighting words"—those which by their very utterance inflict injury or tend to incite an immediate breach of the peace,—are not protected by the First Amendment to the U.S. Constitution. The court ruled that restricting fighting words is permissible because hate speech is not valuable for contributing to greater understandings and because the state has a legitimate interest in limiting disruptions of the peace. Under Chaplinsky, state laws proscribing the public use of racial slurs were deemed constitutional. Since Chaplinsky, however, the Court has limited the scope of the doctrine to incidents in which provocative words are "directed at the person of the hearer" and there is an immediate threat of retaliatory violence (UWM Post, Incorporated v. Board of Regents of the University of Wisconsin System, 1991). In so doing, the court has largely disregarded the first half of the fighting words doctrine, which recognized the injury that racial slurs and other hate speech inflict on hearers.

The Supreme Court has generally struck down laws limiting free speech on the grounds that they are either "overbroad," meaning they restrict speech beyond that which falls under the fighting words doctrine, or are attempts to regulate ideas and content. Speaking to attempts to regulate content, in R.A.V. v. St Paul, Minnesota (1992), the Supreme Court declared that the purpose of the First Amendment is to prevent the majority from expressing its preferences by silencing the minority. Consequently, the high court provided protection for racially hostile speech in public spaces by deeming unconstitutional laws precluding speech simply because that speech is racially hostile.

Academics and legal scholars have responded to the courts by emphasizing the right of individuals to move in public spaces without the fear of racial hostility. These scholars take seriously the harmful effects that racial slurs and closely related actions have on their targets. Many victims of hostile and intense racial slurs suffer physiological and psychological injuries, including high blood pressure, breathing difficulty, nightmares, and thoughts of suicide (McKinney and Feagin 2003; Matsuda 1995). To avoid subjection to recurring racist slurs, people of color often must leave their homes or jobs, which limits their socioeconomic opportunities. Scholars also criticize the Court’s insistence on limiting only words directed at individuals. Because racial slurs dehumanize members of the targeted group, they lay the groundwork for both individual and state-sponsored violence against that group (Ferguson 1995). To take a major example, the German Nazis’ hostile slurs against Jews as vermin and parasites were directly connected to the "final solution" that Jews must be "exterminated."

Prompted by the effects of German Nazi propaganda during World War II (1939–1945), international efforts to regulate hate speech have given far more consideration than have U.S. policymakers to the rights of the targets of such speech. Consequently, the international community has outlawed most racist hate speech (Matsuda 1995, pp. 92, 96). Article 4 of the International Convention on the Elimination of All Forms of Racial Discrimination (1965) declares illegal all propaganda based on ideas of the superiority of one race over another or that promote racial hatred and discrimination. Other human rights treaties, including the European Convention for the Protection of Human Rights and Fundamental Freedoms (1950) and the Inter-American Declaration of the Rights and Duties of Man, (1948) protect people against recurring racist slurs and other hate speech. Similarly, many national governments have outlawed racist speech.

Racialization

The concept of racialization has developed over time. In his 1989 book *Racism*, sociologist Robert Miles described racialization as “a dialectical process by which meaning is attributed to particular biological features of human beings, as a result of which individuals may be assigned to a general category of persons which reproduces itself biologically…. The process of racialization of human beings entails the racialization of the processes in which they participate and the structures and institutions that result” (Miles 1989, p. 76). Earlier, in *The Wretched of the Earth*, the political theorist Frantz Fanon (1925–1961) had described the “racialization of thought” in reference to the failure of early Europeans to recognize that Africans had a distinct culture that was unique to them. Instead Europeans, “set up white culture to fill the gap left by [what they believed was] the absence of other cultures” (Fanon 2001, p. 171). Sociologist Yehudi Webster later defined the concept of racialization as “a systemic accentuation of certain physical attributes to allocate persons to races that are projected as real and thereby become the basis for analyzing all social relations” (Webster 1992, p. 3). Webster goes on to argue that “the second foundations of racialization are provided by social scientific research on race relations, in which the disciplines of history and sociology play an eminent role” (p. 4).

Culture is a key aspect in both Miles’s and Fanon’s definitions of racialization. Historically, there have been intense debates over the issue of race as a social construction versus race based on biology. Omi and Winant addressed the debate and articulated the concept of racialization that many scholars use today. They defined racial formation as “the sociohistorical process by which racial categories are created, inhabited, transformed, and destroyed…. Race is a matter of both social structure and cultural representation” (Omi and Winant 1994, pp. 55–56). This view revolutionized the conception of race as a process and as a social construction.

Critiquing “Racialization”

Some scholars have critiqued current definitions of racialization. Karim Murji and John Solomos, for example, argue that the idea of racialization “has become a core concept in the analysis of racial phenomena, particularly to signal the processes by which ideas about race are constructed, come to be regarded as meaningful, and are acted upon…. Racialization is applied to whole institutions such as the police, educational or legal systems, or entire religions, nations, and countries” (Solomos 2005, p. 1).

Sociologist Joe Feagin argues that “Omi and Winant view the past of North American slavery and legal segregation as not weighing ‘like a nightmare on the brain of the living,’ but rather as lingering on ‘like a hangover’ that is gradually going away” (Feagin 2006, p. 7). Feagin adds that what is “missing in both the mainstream race-ethnic relations approach and much of the racial formation approach is a full recognition of the big picture—the reality of this whole society being founded on, and firmly grounded in, oppression targeting African Americans (and other people of color) now for several centuries. Given that deep underlying reality of this society, all race-ethnic relationships and events, past and present, must be placed within that racial oppression context in order to be well-understood” (p. 7).

Sociologist Eduardo Bonilla-Silva notes that although the perspective of Omi and Winant “represents a breakthrough, it still gives undue attention to ideological/cultural processes, does not regard races as truly social collectivities, and overemphasizes the racial projects … of certain actors (neoconservatives, members of the far right, liberals), thus obscuring the social and general character of racialized societies” (Bonilla-Silva 1997, p. 466). Bonilla-Silva further states:

Although all racialized systems are hierarchical, the particular character of the hierarchy, and thus the racial structure, is variable…. The racial practices and mechanisms that have kept Blacks subordinated changed from overt to eminently racist to covert and indirectly racist. The unchanging element throughout these stages is that Blacks’ life chances are significantly lower than those of Whites, and ultimately a racialized social order is distinguished by this difference in life chances…. The historical struggle against chattel slavery led not to the development of race-free societies but to the establishment of social system with a different kind of racialization. (Bonilla-Silva 1997, p. 470)

In their 2005 book *Racialization*, Murji and Solomos summarize the arguments that suggest that the conception of racialization introduced by Omi and Winant may not have represented a breakthrough:

Barot and Bird feel that Omi and Winant “use the concept of racial formation as a perspective that is not fundamentally different from the concept of racialization as deployed in British literature in the 1980’s…. Miles himself has argued that Omi and
Winant’s conception of racialization is underdeveloped and not used systematically. … Miles and Torres state, ‘Omi and Winant’s defence of the race concept is a classic example of the way in which the academy in the US continues to racialize the world.’” (Murji and Solomos 2005, p. 22–23)

RETHINKING RACIALIZATION

Bonilla-Silva proposes use of “the more general concept of racialized social systems as the starting point for an alternative framework. This term refers to societies in which economic, political, social and ideological levels are partially structured by the placement of actors in racial categories or races” (Bonilla-Silva 1997, p. 469). In rethinking a theory of racial oppression, Feagin suggests three elements: “It should indicate clearly the major features—both the structures and the counterforces—of the social phenomenon being studied; it should show the relationships between the important structures and forces; and it should assist in understanding both the patterns of social change and the lack of social change” (Feagin 2006, p. 7). As the critiques of these scholars suggest, the concept of racialization has changed over time and continues to change.

RACISM

Racism is intertwined with discrimination in two dimensions. On the one hand, discrimination is a specific practice that can arise from racism. On the other hand, racism is a specific form of discrimination directed against a social group that is constructed with regard to physical attributes, for example the color of the skin or the hair type. To these physical attributes specific social features such as behaviors and values are ascribed, thus naturalizing social attributes. Privileges and disadvantages of groups are therefore grounded in nature and gain their legitimacy through this naturalization. The identity of a person is always dependent on the marking, the ascription, and the perception of others. Self and other are defined in a reciprocal relationship: Racism is a specific process of producing self and other (see Darity, Mason, and Stewart 2006). It is the praxis of a dominant group classifying and characterizing an inferior group. Thus some scholars argue that racism transforms political or economical interests into apparently natural facts. Because racism affects social relations, class and race should be examined together (see Hall 1980).

Racism is produced on different levels of societies. On the macro level, racism comes into being through institutional rules, guidelines, and processes of exclusion that are based on and justified by racist discourse. Examples are the Jim Crow laws in the United States, the Nazi regime in Germany, and the apartheid system in South Africa. On the micro level, individual racism comes into being through generalizations, stereotypes, and discrimination against the other’s everyday activities.

The phenomenon of racism existed long before social scientists defined the term. In the 1930s the term racism was first used by the German physician Magnus Hirschfeld (1868–1935) to describe the ideology upon which the Nazis based their identification of the Jews as members of an alien, subordinate, and dangerous race, providing an ideological foundation for the Holocaust (for a wider analysis see Horkheimer and Adorno 1947).

THE DEVELOPMENT OF IDEOLOGICAL RACISM

Ideological racism developed from the processes of construing the human races as apparently homogenous and then building a hierarchy of these races on the basis of ascribed features. These concepts were developed in Europe in the eighteenth century in the context of the Enlightenment and the increased trust in scientific knowledge. Laws of nature were presented as the foundation for differences between social groups, and scientists tried to classify human beings according to categorizations developed in the natural sciences.
Some argue that these classifications based on nature replaced former classifications based on religion, following a trend to secularization. In contrast, Robert Miles and Malcolm Brown argued in *Racism* (2003) that the clash between the idea of biologically constituted different races and the religious belief that all human species descend from Adam and Eve and are therefore homogenous was harmonized by the claim that in response to human sin God damned the sinners and their descendants by distinctive features, such as black skin.

The main impulse to formulate racism as a theory came from French aristocrats striving to get back the privileges they lost in the French Revolution. According to them, the French aristocrats were descendants of the Franconian conqueror, so any restriction of their privileges was a violation of their inherited rights; this idea was formulated as “the legend of the Franconia” by the French historian Henri de Bougainvilliers (1658–1722). Socially different estates in France became referred to as different “races.” In consequence, the privileges of the aristocracy became legitimized not only by the legal system, but also by what were presented as hereditary, physical traits. Charles Darwin’s theory of natural selection and evolution (1863) provided further justification for this theory of the naturally grounded inequality of human beings. The adaptation of Darwin’s theory of evolution to society is called *social Darwinism* (see Hawkins 1997, Dickens 2000). Following this theory, disadvantaged races have their social positions because of their inferior qualities, and those inferior qualities are translated to inevitably lower social status in the common struggle for existence. The idea of a racial hierarchy based on nature became important during the colonization period beginning at the end of the fifteenth century when in the process of oppressing and exploiting Africans, Asians, and Native Americans the supposed racial superiority of whites was established (for a discussion of whiteness, see Bonnett 2000 and Allen 1994).

Racial inequality is a matter of scholarly debate. Some academics argue, with the help of recent genetic research, that there are more genetic variations within races than between them. In this view, races do not naturally exist, but instead are powerful social constructions of racist people (see Miles and Brown 2003). Adherents to this theory argue that there are no clear natural borders between the races; racism itself constitutes these borders and tries to maintain them by ignoring any exceptions. Two crucial aspects of the impact of racism emerge: On the one hand, there is the practice of defining an apparently homogenous group of human beings as a race by negating differences between the individual members of the group; on the other hand, it is essential that the differences between the social groups that are constructed as races are emphasized.

Other scholars argue that the reason for racism is not that there are different races. According to them, racism is caused by the ascription of specific attributes to the races, and they hold that by identifying races as an ideological effect the racial solidarity of the disadvantaged race is undermined.

**PSYCHOLOGICAL EFFECTS OF RACISM AND REFLECTIONS OF RACISM IN THE PSYCHE**

Racism gets its full power by infiltrating people’s own specific perceptions. In the minds of both victims and perpetrators, racism is produced and reproduced with prejudices and stereotypes from the other and the own. It has been widely demonstrated that from the perspective of whites, blacks are seen as violent and criminal. Studies in psychology illustrate that the same behavior pattern is interpreted differently depending on the race of the actor (see, for example, Eberhardt, Goff, Purdie, et al. 2004). From the point of view of whites, a positive action by a black person, like being smart and helpful, often is seen as an atypical event explained by special circumstances, whereas a negative action by a black, like committing a crime or an aggressive behavior, is seen as typical of the genuine personal characteristics of black people. For the actions of whites, the relation is reversed. Claude Steele and Joshua Aronson illustrated the harmful effects of stereotypes when they demonstrated that the mere presence of a question asking the race of those taking an academic test led to a distinct decrease in the scores of participating African American college students: The race question activated negative stereotypes and self-confirming mental representations of poor academic performance. In consequence, the test participants confirmed unwittingly the stereotype that African Americans are intellectually inferior. Different tests showed that the simple activation of race stereotypes had different effects on test performances, depending on the kind of stereotypes (Shih, Ambady, Richeson, et al. 2002).

**RACISM IN THE UNITED STATES**

Because racism depends on economic and political factors, it is important to point out that racism came into being in different forms depending on the historic epoch and geographical region in which it appeared.

**Slavery** Slavery came into existence in China, imperial Rome, and West Africa without relying on racist concepts. However, in the colonial period the ideology of racism was useful in circumventing any of the conquerors’ religious or moral considerations that would make all human beings equal before God and thus require that they be
treated equally by man. Using racist arguments, white conquerors could justify slavery, the use of slaves as property, the destruction of their social and cultural identities (Patterson 1982), and their exploitation. This was possible because the conceived hierarchy of races presented the whites as superior to other races; from a racist perspective, human beings are not equal and therefore they can be treated unequally.

The main reasons for the growth of slavery were economic. Slaves were used as a cheap labor force and as a profitable trade good. In the United States the profits acquired through slavery were an important factor in the growth of the shipping industry and a source of surplus wealth for early industrialism. Slaves worked in households, in mines, and on sugar and cotton plantations in the southern states of North America, in Brazil, and in the Caribbean. Most of the 4 million slaves in 1860 were the property of a small upper class in the U.S. southern states, and for this elite, their own economic power was bound directly to their property of slaves. They justified slavery by identifying blacks as a weak race that had to be protected by the slave owners, who knew how to treat them according to their natural status.

Before the end of the slave trade in the mid-nineteenth century, between 11 and 15 million Africans were enslaved and transported to Europe and South, Central, and North America. Most of them were enslaved during the eighteenth century, and most came from the West African coast and from central Africa.

After the Civil War After the U.S. Civil War (1861–1865) slavery was legally banned in 1870 by the Fifteenth Amendment to the Constitution. Because there was no land reform most African Americans were solidly concentrated in the southeastern states, nominally free but economically tied to the same cotton lands and the same employers as before the war. Former slaves were still stigmatized and pressed into economic poverty. From the perspective of racist whites in the northern and southern states, African Americans were an inferior race without the right to participate equally in political and social life. After the end of slavery in the United States racism took shape in the oppression of the African American population and in defining them as a subordinated race.

Discriminatory practices continued in the United States; the Jim Crow laws (1890–1912) banned African Americans from public places, curtailed their educational rights, and allowed widespread violence against people of color, including the lynching of more than 3,000 African Americans in the southern states between 1882 and 1936. Clandestine organizations such as the Ku Klux Klan murdered and harassed African Americans.

The Twenty-First Century The civil rights movement in the United States led to the passage of the Civil Rights Act of 1964, ending institutionalized racism in the United States. However, racism is still alive; the durability of ideological racism and the idea of naturally based inequality between races still is present in the attribution of social traits to racial groups. In consequence, economic and educational opportunities are still unequal between the races. African Americans are still put into a position of inferiority in the hierarchy of races; an expression of this is segregation in urban ghettos (see Massey and Denton 1993 and Wilson 1987). Racist discourse still exists and reproduces itself in the stereotypes; it is part of everyday discrimination, and it leads to different chances for access and participation in the contemporary United States and elsewhere.

RADCLIFFE-BROWN, A. R.
1881–1955

Alfred Reginald Radcliffe-Brown was a British anthropologist closely associated with the development of structural-functionalism. His firm theoretical framework and his administrative skills helped to consolidate social anthropology as an academic discipline across the British Commonwealth.

Defying his impoverished lower-middle-class beginnings, Radcliffe-Brown enjoyed an elite academic education at Cambridge University, where A. C. Haddon (1855–1940) and W. H. R. Rivers (1864–1922) were his mentors. He first wanted to study natural sciences, but was directed toward "moral sciences" (comprising philosophy, psychology, and economics). Yet his leanings toward the natural sciences remained with him throughout his career, and the use of analogies between social structures and structures occurring in nature are emblematic of his style of thought. At the same time, he was able to combine his insistence on "structure" with a flamboyant way of dressing and a fascination with Peter Kropotkin’s (1842–1921) anarchism, earning Radcliffe-Brown the nickname "Anarchy Brown."

Most of Radcliffe-Brown’s adult life was spent outside England. He conducted ethnographic fieldwork in the Andaman Islands (1906–1908) and Western Australia (1910–1912), but never achieved the kind of in-depth familiarity with local settings that would soon become typical of social anthropology. Radcliffe-Brown’s influential academic career began in 1920, when he became the founding professor of social anthropology at the University of Cape Town in South Africa. He went on to become founding professor at the University of Sydney (1926–1931), professor at the University of Chicago (1931–1937), and chair of social anthropology at the University of Oxford (1937–1946). He continued lecturing at universities in Brazil, Egypt, England, and South Africa, and served as president of the Association of Social Anthropologists until shortly before his death.

Even by his own account, Radcliffe-Brown was a slow writer. His only monograph is The Andaman Islanders (1922); the rest of his publications are articles and lecture transcriptions. Although his academic career spanned half a century, Radcliffe-Brown’s theory remained more or less unchanged throughout. He constantly systematized the idea that social anthropology should become a “natural science of human society” through empirical investigations of social structures. Comparisons between different societies should enable anthropologists to discover universal and essential relations; apparent diversity should be reduced to clear classifications. Anthropology should focus on directly observable networks between persons, and distill “general structural forms.” Rejecting diffusionism, evolutionism, and any kind of “conjectural history,” Radcliffe-Brown was also critical of the concept of “culture,” which for him was a foggy abstraction and subordinate to social structure.

Assessments of Radcliffe-Brown’s contribution to anthropology tend to be polarized. He was a charismatic lecturer, able to impress upon others a habitus of scientific rigor. Even some streams of American anthropology, with its longstanding emphasis on culture and historical particularity, were influenced by him. But just as much as he united scholars during his lifetime, his name soon became synonymous with an overly rigid and intellectually unsatisfying approach that no one wanted to follow anymore. From the 1950s onward, all major figures in British social anthropology, notably E. E. Evans-Pritchard (1902–1973), Raymond Firth (1901–2002), and Edmund Leach (1910–1989), denounced Radcliffe-Brown’s theory as unable to grasp history, social change, and unequal relations of power. That he wanted anthropology to become a “natural science” attracted particular scorn (e.g., Leach 1976). Even if Radcliffe-Brown’s importance for the discipline is now widely seen as historical, his emphasis on observable social networks, as opposed to cultural values, retains a certain influence, especially in Britain.

RADICALISM

The word *radical* has a number of meanings, one of which involves “getting to the root of the matter.” This analogy is helpful in focusing attention on the key characteristics of the term, and on its various usages within social science. When people talk about “radicals,” they mean those who take ideas and concepts back to first principles. They are those who are unafraid of laying bare what is hidden, subterranean, or uncomfortable to discuss. Radicals do not mind upsetting the status quo, received wisdom, or “common sense” conceptions of any kind. To talk about radicalism is therefore to talk about the belief systems of radicals. Yet what is it that characterizes radicalism, and how does this impact our understanding of knowledge generally?

As is clear from the above, radicalism is not a concept that denotes a particular set of ideas or a particular approach, in the manner of many other terms in the lexicon of social science. When one discusses Marxism, it is clear that this relates to the word and ideas of Karl Marx and his many followers. The same cannot be said of radicalism, which is a concept that is positional or contextual. Whether a given ideology or stance can be regarded as radical depends on where it stands in relation to dominant or “accepted” ideas. Thus a “radical conservative” (if this is not an oxymoron) is someone whose radicalism is defined in relation to dominant conservative ideas. He or she wishes to get to the “root” of conservatism, or of the problems discussed by conservatives. Radical conservatism is therefore not inherently radical, it is only radical in relation to other conservative ideas. Likewise, radicalism only exists insofar as there are ideas that are mainstream, orthodox, and widely accepted.

Radicalism can also be regarded as contextually dependent. In other words, whether a set of ideas is radical depends on the context in which these ideas are being offered or pursued. Many ideas that were once perceived to be radical have, over the course of time, come to be regarded as mainstream. Thus, radicalism should be understood less as a description of a core orientation of the kind associated with labels such as “Marxist,” “liberal,” or “conservative,” and more as a set of ideas that is inclined to query orthodoxy, whether it be secular, religious, social, or scientific. A starting point of this article is thus the contention that radicalism does not denote a particular set of ideas or arguments, but rather any ideology or position that takes issue (or appears to take issue) with settled, accepted or otherwise mainstream views. Some examples will help to clarify the above.

RADICALISM AS POSITIONAL AND CONTEXTUAL

As mentioned above, radicalism does not denote a particular set of ideas or arguments, but any argument that takes issue with accepted positions, however defined. In this positional sense, radicalism can be mapped in terms of certain well-known debates. To take an obvious starting point, Darwin's account of evolution was once regarded as radical (as well as absurd and despicable) by mainstream commentary. However, from the late nineteenth century onward, more and more scientists in the West began to hold Darwinian views. A great deal of the evidence, from a wide variety of scientific and social scientific investigations, seemed to support the view that evolution takes place over very long periods of time and can be adduced to random genetic mutations. Darwinism, therefore, once a radical and heretical doctrine, became mainstream science. Likewise, those who opposed Darwinism, such as Christians and other religious groups, were once in the majority, but over the course of a century or so they became “minoritarians” in relation to issues in basic science. One might ask whether Darwinism or intelligent design should now be regarded as the more radical position. This is a moot point, however. In areas or communities that are deeply committed to a deist view of the universe, Darwinism remains a radical doctrine to be combated wherever possible. To Darwinists, the claims of creationists are radically conservative.

It is often held that radicalism is necessary because progress is impossible without challenges to orthodoxy. Thus, philosophers of science frequently reserve a special place for radical ideas as necessary, and indeed desirable. This usually comes with the caveat that radicals submit to the norms of falsification and experimentation. Radicalism can be good if it is seen to be in tune with the general tenor of scientific understanding, but it is less so when it appears to take issue with a certain set of expectations. Albert Einstein's radicalism is useful on these terms, for example, but Sigmund Freud's is less so, at least according to figures such as the philosopher Karl Popper (1902–1994). Those who oppose such a conventional view of scientific progress, such as Jean-François Lyotard (1924–1998) and Paul Feyerabend (1924–1998), are themselves regarded as radicals by philosophers of science and social science because of their insistence on the relativism of knowledge claims. This kind of radicalism equates to the view that science does not deserve the special status many accord it, for it is merely one kind of “nar-
“radicalism” to set alongside other narratives—such as “Creationism”—that claim to offer privileged access to the true nature of things.

**FROM SCIENCE TO IDEOLOGY**

More generally, there have always been radical views that have challenged or undermined the mainstream. The twentieth century, for example, is often noted for the variety and impact of unorthodox, extreme, and nonmainstream views that surfaced during this period. To illustrate the way in which radicalism is context-dependent, the century can be divided up into four periods: the interwar years; the postwar era up to the oil crisis of the mid-1970s; the period of conservative preeminence to the fall of the Berlin Wall; and finally the period of the “Post–Cold War Order,” which carried over into the twenty-first century. Traversing a century of radicalisms will illustrate the changes in the nature and form of radicalism from modernity to what is often termed “postmodernity” or a “second” modernity.

In the interwar years (1918–1939), the world witnessed an astonishing burst of radicalism, radical parties, and radical politics. This was due to a number of factors, principally the impact of war, the rise of capitalism, and the perceived shortcomings of individualism. The radicalism of the Russian Revolution came out of a deep discontent with the inherited monarchic order. Bolshevism promised a world without hunger, hierarchy, or war, and a world without capitalism, individualism, or imperialism. The rise of Hitler owed a great deal to similar sentiments, although it translated into a different set of demands. Nevertheless, radicalism in this period meant collectivism, as opposed to individualism; state control, as opposed to the free market; and universalist claims, in the name of “proletarian internationalism” or Aryan superiority. The individual counted for little when compared with the needs of the class or the race. This common set of characteristics offered commentators such as Hannah Arendt, Karl Popper and Carl J. Friedrich license to roll up these otherwise diverse radicalisms into one overarching phenomenon: “totalitarianism.” This was a radicalism that threatened the annihilation of prevailing orthodoxy, whether characterized as liberal or conservative.

In the postwar period (1945–1975) the dominant or mainstream ideology in most Western states was that associated with the work of the British economist John Maynard Keynes. The “postwar consensus” insisted on the growth of the public sector or welfare state, the extension of basic rights and liberties (as announced in the UN Charter), and the pursuit of policies of growth through the management of demand. Social-democratic or welfare-state thinking became dominant across the developed world.

In terms of political ideas and positions, “radicalism” at this point referred to two main tendencies: those who were opposed to Keynesian because it was too statist, and those who argued that it was not statist enough. With regard to the former, the period is noted for the emergence of neoliberal ideas associated with figures such as Friedrich von Hayek, Milton Friedman and, later, Robert Nozick. Their radicalism consisted in the suggestion that the welfare state was despotic and heralded the end of choice, the end of the individual’s control over his or her fate, and the elimination of the entrepreneurial and risk-taking characteristics upon which economic growth depended. The state should give way to the market, they believed, not the other way around. At the same time, considerable interest developed in models of socialism that radicalized the terms of the postwar consensus while also seeking to avoid the perils of communist dictatorship. Multiple left-wing radicalisms emerged and flourished (e.g., The Frankfurt School, situationism, Maoism, “humanist Marxism”), reflecting the “postmaterialist” discontent with both Western and Eastern society that was to be such a feature of the late 1960s.

Other kinds of radicalism arose in this period out of the desire for “liberation,” particularly liberation from racism, colonialism and, “patriarchy.” Antiracism became a powerful current and gave birth to a number of radical groups and figures across the developing and developed world, including the Black Panthers, Malcolm X, and various figures in the civil rights movement, such as Martin Luther King Jr. Anticolonial or postcolonial demands were articulated in the work of writers such as Paolo Freire, Frantz Fanon, and Jean-Paul Sartre, while radical anticolonial movements swept the globe, led by figures such as Che Guevara and Ho Chi Minh. For feminists, the problem was the “patriarchal” assumptions of mainstream political theories and practices. “Radical feminism” spared little in its critique of the exclusionary and demeaning character of patriarchal practices. Women had to assert not equality, but their difference from men. This entailed developing novel and inclusive strategies in relation to oppressive discourses wherever they were found.

The oil crisis of 1973 and 1974 was followed by a period of conservative preeminence, which put into relief what was at stake in these ideological battles and allowed advocates of what had been regarded as a deeply radical position to win support in the mainstream. In a matter of a decade, neoliberalism moved from being a deeply heterodox and radical position to being “common sense”—as described by prominent advocates such as Margaret Thatcher and Ronald Reagan. Orthodoxy now shifted away from being protective of public services and demand-fuelled economic growth, moving toward a position hostile to the welfare state, “dependency culture,” and public spending. This, in turn, encouraged a new set
Radicalism

of radicalisms highlighting the perceived shortcomings of the prevailing political orthodoxy. Chief among these was the emergence of environmentalism. Associated with figures such as James Lovelock, who developed the “Gaia hypothesis,” E. F. Schumacher and Ivan Illich, environmentalism was a response to the oil crisis and the perception that there were structural “limits to growth.” The problem was not too little market, as advocated by the neoliberals, but too much. In particular, there was too much unfettered market activity in relation to scarce natural resources.

There was also a change in the morphology of radical activism during this period, coinciding with the decline of the mass party in the wake of the emergence of so-called new social movements. These movements were much more diffuse than mass parties, less ideological, and often very radical. This radicalism expressed itself in terms of a rejection of mainstream political processes in favor of “direct action” or DIY (do-it-yourself) practices.

The era of the “Post–Cold War Order,” which began with the fall of the Berlin Wall in 1989, has witnessed an explosion of radicalism in response to widespread discontent with several new orthodoxies, particularly the “Washington Consensus,” associated with the extension of neoliberal policies to many different areas of economic and social activity; the idea of the “clash of civilizations,” positing an inevitable conflict between cultures; and the continuing dominance of individualism and consumerism.

In the 1990s an “antiglobalization movement” emerged in response to the neoliberal ideology that had come to prominence. This involved a panoply of radicalisms—some old, some new—all responding to the perceived shortcomings of the free-market policies pursued by global institutions such as the International Monetary Fund (IMF), the World Trade Organization (WTO), and the World Bank. The antiglobalization movement gives witness to one of the more remarked-upon features of the contemporary period, namely the proliferation of radical currents and energies, as opposed to their crystallization within mass parties united by a single ideology. This is not to be mistaken for the “end of ideology,” as long lamented by cultural commentators such as Daniel Bell, Herbert Marcuse, and Francis Fukuyama, but rather the proliferation of ideologies, some of which are radical, while others are much less so.

Samuel Huntington’s “clash of civilization” thesis is perhaps both a result and a cause of the profusion of cultural and political radicalisms across the world. This is paradoxical in the same sense that globalization is, for while globalization seems to be drawing people closer together, it also renders “local” resistance more intense and radical. Thus, key radicalisms that emerged at the start of the twenty-first century include neoconservatism and Islamic fundamentalism. Both are responses to perceived isolation and cultural embattlement: the former in defense of values associated with the imperiled Greco-Roman civilization; the latter in defense of an ever more literal reading of the Qu’ran. Each faces the other as a defensive response against incorporation into what are perceived to be homogenizing global forces beyond the control of distinct nations and cultures.

More generally, any set of ideas that challenges the supremacy of the free market, of dominant interpretations of ideals such as equality and freedom, or of the idea of the individual as preeminently a consumer will be perceived by the mainstream as “radical.” In this sense, there are many sources of radicalism, including religion (and not just Islam). There has also been a rise in the influence of all manner of fundamentalisms, New Age ideas, alternative therapies and perspectives, and postmaterial ideas and ways of living that stress the need to escape from the dominant ethic and values.

FROM MODERN TO POSTMODERN RADICALISM?

In the political sense, radicalism has ceased to express itself on the same terms that marked the radical currents of the twentieth century. Radicalism had one goal during that period: the transformation of the existing world into a world that would, so it was claimed, be markedly better than the one displaced. Today’s radicalisms are rarely built from such certainties. Nor are they, in the main, built on the kinds of universalist ambitions that characterized earlier radicalisms. Instead, they are partial, sectional, particularistic, local, and fragmented. Where commentators once lamented the prospect of being engulfed by a singular countervailing radicalism (“totalitarianism”), there are now many radical currents and tendencies—some benign, and others much less so. Orthodoxy, however defined, does not have one rival but many, and radical ideas are often resolutely minoritarian. Ideas, positions, philosophies, and therapies no longer seem to harbor the ambitions of modernity, to transform the world itself. What they demand is a space of “difference,” a space in which heterodoxy, otherness, and particular identities and positions can stand apart and flourish.

These “postmodern” radicalisms are modest, even parsimonious, in relation to the claims they make for themselves. With the “end of grand narratives,” as Lyotard put it, many radical groups and movements have evidently lost or abandoned that sense of certainty that was such a hallmark of the ideologies and movements of the twentieth century. In a world of skeptics, radicalism (as expressed in the ideas of the leftist Zapatistas in Mexico, for example) can only be sustained by thin or partial
affinities and affiliations, by appeals to shared “intuitions” and the desire for “dignity.” This is hardly the basis for the kind of mass mobilization hoped for by yesterday’s radicals, but it seems to be enough to sustain the radicals and radicalisms of today.

In sum, radicalism is not on the wane or in danger of being made redundant by an overarching conformity to ideas and values, no matter how expressed (as per Fukuyama’s “end of history” thesis). Any such view reveals a certain naivety about the role of ideas in history. As this brief overview suggests, mainstream and conventional ideas are always faced by ideas that challenge or undermine them. Indeed it makes little sense to talk about “the mainstream” or “the conventional” without reference to ideas or positions that lie outside them. Radicalism is, in simple terms, the name given to whatever is different, challenging, or otherwise difficult to digest. As such, radicalism is just as much a feature of contemporary life as is the status quo, however defined.

**RADIO TALK SHOWS**

Radio talk shows can be defined as radio broadcasts centered primarily on conversational speech. They encompass numerous discourse genres and formats, ranging from political diatribes to highly interactive exchanges with members of the listening audience. Many talk shows have hybrid formats featuring music, sound effects, and news interspersed with interviews, debates, social and political commentary, religious exegesis, medical advice, therapeutic discourse, question-and-answer sessions, sports-fan exchanges, and storytelling.

Talk shows are typically hosted by a single radio personality, usually positioned as an expert in some area. Many also feature occasional guests who are interviewed, as well as one or two regular interlocutors who assist the host. Audience participation is usually a major feature of talk radio shows worldwide, with opportunities for listeners to telephone or write to the program host with questions, comments, or music requests, which are then relayed on air. The place of talk radio in non-Western nations parallels the role of talk radio in Western nations, yet it is a relatively new area of exploration that merits more in-depth research.

The social consequences of talk radio are extensive. Three major types of impact can be identified. First, talk radio has far-reaching implications for the nature of the public sphere in modern societies as it creates forums for participatory democracy and the development of public opinion. Second, talk radio influences both everyday discourse and political discourse by providing models of talk and by setting agendas through talk. And third, talk radio has become a major part of everyday life for countless people around the globe as they structure their days around favorite programs and as they develop affective ties to radio personalities.

**HISTORY**

Talk shows have been a prominent feature of radio since the inception of broadcasting in Western nations in the 1920s and in non-Western contexts from the 1940s onward. Early examples include Alexander Woolcott’s (1887–1943) urbane commentary on New York’s WOR in the 1920s and Walter Winchell’s (1897–1972) political gossip program on NBC in the 1930s. More interactive formats emerged in the 1930s, first with *vox populi* “man on the street” interviews being taped and then later relayed on air, and then with radio “town hall meetings,” which featured live broadcasts of studio audiences discussing current events. Such formats were also introduced in colonial broadcasting in Africa as early as the late 1940s. In the United States, radio call-in programs began in the mid-1940s. Precursors of talk radio formats and functions include public traditions such as town hall meetings, and gathering places such as literary circles, coffee houses, village squares, and beer gardens, as well as mass entertainment forms, such as vaudeville and circus sideshows.

Between the early 1980s and the mid-1990s, the number of radio stations in the United States featuring...
talk radio quadrupled. By the mid-1990s, talk radio ranked as the second most popular radio format in the United States, with country music being the first. The dramatic rise of talk radio during this period is attributed to several factors, including a general collapse of public life in the United States, coupled with an increased predictability and absence of personality in FM radio programming. Some scholars have argued that Americans found themselves increasingly isolated and thus turned to talk radio as a way to be connected to community and to others. Similar arguments have been made about talk radio in other parts of the world, such as England and Israel.

During the 1980s, certain AM stations as well as National Public Radio (NPR) strategized to “reactivate attentive listening” (Douglas 1999, p. 286) through less predictable formats, more chatty ad-libbing, and greater emphasis on sound effects and voice qualities. Further contributing factors to the prevalence and popularity of talk radio at the end of the twentieth century include the increased facility of national broadcasting afforded by satellite technology and the increased facility of audience interactivity afforded by cell phones. A final factor relatively unnoticed by scholarship is the fact that countless radio listeners are engaged in lengthy commutes to and from work. Morning “drive time” talk radio formats as well as evening news magazines fit into these lifestyle patterns and relieve the boredom and isolation of commuting for long periods every day.

CONTEMPORARY TRENDS
Approximately 80 percent of all U.S. radio stations include some form of talk radio in their programming. Many stations, such as NBC’s Talknet, ABC’s Talkradio Network, and Air America Radio, are exclusively devoted to round-the-clock live talk programming. NPR also features a substantial number of entertaining and informative talk programs, such as All Things Considered, Talk of the Nation, Car Talk, and A Prairie Home Companion.

While the genre of talk radio might be best known for its strong language, irreverence, and polarizing discourse, encapsulated in the persona of the shock jock, the majority of talk radio programs worldwide do not adhere to this model. Examples of the former in the United States include broadcasters Howard Stern, Rush Limbaugh, and Don Imus. As with many shock jocks, these individuals and their stations have been subject to investigations by the Federal Communications Commission (FCC), a governmental regulatory body, and some have received fines and suspensions for pushing the limits of respectability on the airwaves.

By contrast, most of the world’s talk show hosts, including those in the United States, are models of respectability. They work to build community, air common concerns, solve problems, and develop better futures for their listeners. In many African nations, for example, talk radio programs play a significant role in informing people about electoral processes, debating political issues, and allowing citizens to air their views. One dramatic case of talk radio in the service of democracy in Africa is exemplified by the Talk Mogadishu program on Somalia’s station, HornAfrik. On this program, listeners from different parts of the city call in to update each other on events across the chaotic, war-torn city landscape. In addition, they pose pointed questions to rival warlords who appear as program guests. Other examples include the popular talk shows on Zambia’s national radio station. Two Bemba-language programs, Baanacimbwusa (Women Advisors) and Kabuusha Takoletuwe Boowu (a proverb meaning “the inquirer was not poisoned by a mushroom”), are inspired directly by indigenous modes of advising. In the former, the host introduces a topic concerning family and marriage, which a panel of elder women then discusses. In some cases, the topic is developed from a listener’s letter. In the Kabuusha program, an expert advisor answers listeners’ letters on a variety of subjects, including corrupt politicians, adulterous spouses, in-laws who demand more marriage payments, and employers who exploit their workers.

In their capacity as important avenues for influencing public opinion and voting behavior, talk radio programs have attracted the attention of politicians in numerous contexts worldwide. In the United States, for example, talk radio contributed to a coordinated popular protest against a proposed congressional pay raise in 1989. It continues to be a vital influence on the tenor of presidential campaigns, cabinet and Supreme Court nomination hearings, and the reception of government policies in general. In contexts where there is less media freedom, political radio talk show hosts often risk charges of sedition, physical threat, or forced exile, as recent cases from Uganda and Haiti attest.

CRITICISMS, CONCERNS, AND PROSPECTS
Critics of talk radio describe it as a debased form of journalism and public discourse. Their concern is that personal opinions and private experiences are emphasized over relevant facts and information. Listeners are thus not enlightened in ways that allow them to develop informed opinions. In this analysis, talk radio is not about citizenship or participatory democracy, but about sensationalism and ratings. Other criticisms include an assessment that hosts with call-in programs simulate a model of authentic dialogue, but in reality are engaged in a complex form of social control and norm making. These criticisms are well
founded when applied to certain forms of talk radio, particularly the shock jock genres, but detract from the fact that a multiplicity of talk radio genres also work to foster positive social change, personal growth, and enjoyable listening experiences among audiences.

Talk radio will continue to be a vibrant and multifaceted hybrid genre well into the future. The recent emergence of Internet radio and Internet telephoning is already yielding many more possibilities for talk radio formats and talk radio communities, including global talk radio. Coupled with the rise of other participatory and audience-produced media such as blogs and wikis, talk radio will continue to be a media form that allows audiences to “be the media” and thus have an impact on the tenor of political life and communication environments more generally. From ice hockey fan exchanges to dialogues on compassion in Zen Buddhism, talk radio provides an important area of scholarly inquiry as it touches on virtually every field of the social sciences, including media studies, cultural studies, anthropology, sociolinguistics, social psychology, and political science.

RAILWAY INDUSTRY

A railway industry is a group of companies that transport goods (freight) or individuals (passengers) by railcars from one place to another. Locomotives pull or push railcars (containing freight or passengers) over rail tracks. Railways enhance the access consumer and resource markets have to goods and individuals, which in turn contributes to economic development and rising land values, and influences industry locations.

Even before the advent of locomotives, horse-drawn railcars (or tramways) were an improvement over other means of land transportation—the resistance encountered by a wheeled vehicle traveling over smooth rails is less than with non-smooth roadways. By the late eighteenth century, tramways were commonly used in the United Kingdom for transporting coal. The first tramway in the United States appeared in Boston in 1807. Experiments with steam-driven rail locomotives began in the 1820s. By the middle of the nineteenth century, steam locomotives had made the railway industry the world’s dominant provider of land transportation. Steam locomotives, in turn, were subsequently replaced by diesel locomotives.

Freight railway companies are primarily transporters of bulk commodities (such as coal, chemicals, and grain) over relatively long distances. By comparison, trucking companies are transporters of manufactured commodities over relatively short distances. In the United States, railway companies generally incur less cost than trucking companies in transporting goods at a distance of five hundred or more miles. Passenger railway companies provide intercity transportation service, moving individuals from one city to another. Rail service for passengers traveling within a city or to and from a city and its suburbs is provided by urban transit companies.

Governments in many countries have assisted in the early expansion of the railway industry. Forms of government assistance include government ownership, outright donations, tax exemptions, and loans. This assistance stimulated railway construction and, in turn, economic development. At the same time, many projects were undertaken that were not economically justified, resulting in an overexpansion of the railway network.

Cheap labor also stimulated the early growth of the railway industry. Chinese laborers were hired by the Central Pacific Railroad Company in 1863 to build a section of the U.S. transcontinental railroad over the Sierras and into the interior plains. They worked for meager wages through harsh winters and under dangerous working conditions. Convicts and slaves also built railways in the United States and in other countries.

Eric Williams (1944) has argued that, because the African slave trade was instrumental in U.S. and British economic development, it indirectly stimulated the expansion of railway networks in the United States and Britain. This claim was countered by Stanley L. Engerman (1972) through what is called the “small ratios” argument, which maintains that slave-trade profits were too small to stimulate British industrialization. In response to Engerman, William Darity Jr. (1990) argues that there are several growth and trade theories supporting a prominent
role for the African slave trade in British industrialization that cannot be dismissed or disproven by the small ratios argument.

An earlier application of the small ratios argument by Robert Fogel (1964) focused on the economic history of the railway sector itself. As part of his development of an overarching hypothetical picture of American economic growth without a transport revolution, Fogel sought to demonstrate that the revenues generated by the railway system as a percentage of gross domestic product were too low to have been decisively important. But Fogel’s argument is subject to the same response that has been given to Engerman’s attempted refutation of the Williams hypothesis: While it is true that the revenues or profits of any single sector as a percentage of total national income generally will look “small,” the critical consideration is the full impact of the sector via its linkages with numerous other productive sectors forming the economy.

To protect the public against monopoly-related abuses, railway companies were often economically regulated by government. In the United States, for example, the 1887 Interstate Commerce Act established the Interstate Commerce Commission (ICC) to economically regulate interstate railway transportation service. Economic regulation of railways may include rate/fee regulation, entry regulation, service regulation, and financial regulation. Rates (prices for freight service) and fares (prices for passenger service) charged and entry into the industry are subject to approval by the regulatory commission. Freight and passengers are to be delivered in the same physical condition as received. Various financial aspects of the railway industry, such as mergers and accounting systems, are also regulated.

Government assistance and regulation aimed at economic development and protection of the public interest may also restrict competition. In the United States, restrictions on “intermodal” competition (i.e., between two modes of transportation, such as railways and trucking) have contributed to a decline in the U.S. railway industry, exhibited by a decrease in industry market share and return on investment. In 1945, 67.2 percent of the U.S. domestic intercity freight traffic (in ton-miles) was transported by railways and 6.5 percent by truck; by 1975, 36.7 percent was transported by rail and 22 percent by truck. The rate of return on net investment for U.S. Class I (the largest) railroads was 4.7 percent in 1944, but declined to 1.2 percent in 1975. Regulation suppressed intermodal price competition and the abandonment of excess track capacity.

In the 1970s the U.S. Congress responded to the decline in the railway industry by creating Amtrak (the National Railroad Passenger Corporation) to take over all rail passenger-service lines over seventy-five miles in length, and Conrail (a government corporation), to operate the freight service of seven major Northeast railways in bankruptcy. The Staggers Act of 1980 partially deregulated the industry by providing railway companies with greater opportunities to compete and thus reverse the industry’s decline. Specifically, the Act provided greater pricing freedom and reduced the time permitted for the ICC to make merger and track-abandonment decisions.

The U.S. railway industry, its shareholders, and most shippers have benefited from deregulation—the industry’s share of intercity freight traffic (in ton-miles) increased to 41.7 percent by 2001, the rate of return on net investment for Class I railroads increased to 6.1 percent by 2004, and real railway prices (adjusted for inflation) have declined. On the other hand, labor has been harmed. In 1975 the industry had 548,000 (488,000 Class I) employees; by 2004 the number had declined to 226,000 (158,000 Class I) employees. These job losses are attributed to industry restructuring and the increased use of technology.

The United Kingdom has sought to promote competition in its railway industry by privatizing the government-owned British Railways (BR) through passage of the Railways Act of 1993. The ownership and control of infrastructure were separated from train operation. Infrastructure was placed under the control of a new government company, Railtrack, in 1994, but in 1996 BR’s freight-train operations (including rolling stock) were split into six companies and sold to the private sector. Passenger train operations were not sold, but were franchised to twenty-five private-sector train-operating companies. Under privatization, however, government subsidization of the railway industry has more than tripled, due to subsidies to passenger franchises and to Network Rail, the company that replaced the collapsed Railtrack. The numerous private freight-operators that have entered the market have resulted in more competitive freight operations. The four remaining freight-operators are profitable.

The European Commission (EC) is seeking to liberalize the national railways of its European Union member-states by creating a single market for rail transport through the removal of barriers to cross-border freight and passenger rail traffic. Specifically, the EC is seeking to separate the control of rail infrastructure from operations, to eliminate physical differences among national railways (e.g., with respect to signaling, electrification, and operating rules), and to open the market up to competition. The entry of numerous private freight operators into the market has forced the national railways to become competitive.

An important challenge facing railways in many countries is to provide enough capacity to keep pace with the growth in world trade. The volume of ocean-container shipments is growing worldwide at the rate of 9 percent
per year, thereby overburdening the infrastructure of railways that transport containerized cargo to and from ports (i.e., railways engaged in intermodal traffic). Today, the largest share of the cargo mix for U.S. railroads is intermodal cargo. In Canada, a shortage of intermodal rail cars has resulted in congestion (or traffic delays) at a number of its ports. Intermodal rail service in China has numerous problems, such as lateness and cargo damage.

RAINBOW/PUSH COALITION
SEE Coalition.

RAJ, THE

The *Raj*, a Hindi word meaning “rule,” is the epithet most closely associated with British rule of the Indian subcontinent. While the English East India Company (EIC) had been present in South Asia from the early seventeenth century, formal British rule began in 1757. The British finally left the subcontinent in 1947, ceding independence to the new states of India and Pakistan on August 14/15. The latter included Bangladesh as East Pakistan, which gained independence in 1971. The period of the Raj covers two hundred years of South Asian history and is one of the most important episodes of colonialism in modern history.

THE EAST INDIA COMPANY (1757–1858)

The origins of British rule of South Asia lay in the founding of the English East India Company (EIC) in 1600. The company’s participation in the lucrative spice trade led it to establish trading posts first at Surat on the Gujarati coast and later at Bombay, Madras, and Calcutta. By the mid-eighteenth century, competition with the French drew the British into the South Asian political scene through alliances with local powers. Political instability following the disintegration of Mughal authority enabled the EIC to transform from a mere trading interest to a territorial ruler. The company exercised power indirectly through local allies and rulers, setting a precedent followed up to 1947.

The indirect exercise of control contributed to the hybridity of EIC governance. An English trading company driven by European ideas of economy as well as European norms and practices of political authority, the EIC was also a participant in the South Asian political universe, asserting its credentials as a successor state to the Mughal empire. It continued to transact the business of government through local allies, according to local custom and in local languages. The company made an extensive effort to codify indigenous law and practice. Yet this effort to preserve and participate in Indian “traditions” fundamentally transformed them. The EIC became the ultimate arbiter of what constituted tradition, and its codification turned previously fluid arrangements of social interaction into rigid systems of social classification. Throughout its reign, the debate as to whether the company’s role was to transform Indian society or to preserve Indian tradition continued unabated.

THE GOVERNMENT OF INDIA (1858–1947)

Company rule ended with the abolition of the East India Company in 1858 in the wake of the Indian rebellion, more commonly known as the Indian Mutiny. The revolt convinced the British that their efforts at reform of Indian society had been dangerously miscalculated. Consequently the Government of India (GoI) understood its role in an extremely conservative light. India was to be governed for the benefit of the British metropole as cheaply as possible. The GoI’s mission was thus to preserve stability and control, largely through a strategy of “divide and rule.” Government was to be exercised...
through a collaborative elite responsible for the implementation of government policy in the locality.

The emergence of a national political discourse in the late 1800s came about against the wishes of the GoI, but on a stage prepared by it. Only in a society penetrated by contemporary European ideas of nationalism and tied together by modern communication and transportation technologies could the conceptualization of an “Indian” political community emerge. That conceptualization was dominated by the all-India Congress, initially a vehicle for the collaborative elite to advocate their interests. By the turn of the century however, Congress began to transform itself from a party of collaborators to a party advocating home rule (swaraj) and eventually independence. During the First World War, Indian nationalists promised their support in exchange for guarantees of postwar political movement. They were bitterly disappointed as the expected peace dividends dissolved in the face of a reassertion of imperial control. The 1920s witnessed the transformation of the Congress and Indian nationalism into a mass political movement. This change was largely engineered by Mohandas Gandhi (1869–1948), who organized mass campaigns of civil disobedience built upon a cross-communal political platform of Indian nationalism. Gandhi’s efforts redefined the bounds of India’s public political space, including parts of society, such as women and so-called untouchables (dalits), previously excluded from political participation. Yet local elites proved wary of the perceived peasantization of politics and the erosion of their autonomy by the nationalist cause.

The preeminence of Indian nationalist discourse was threatened by communalist politics, progressively more prominent from the late nineteenth century. India’s formerly plural religious traditions became increasingly standardized, hardening the boundaries between them. The Anglo-Indian judiciary arguably played the primary role in the standardization of the diverse traditions of India’s various communities, in turn leading to the solidification of communal borders. As the colonial state became more involved in civic disputes through the course of the nineteenth century, it increasingly usurped the spaces formerly regulated by communal “tradition” and “custom.” Faced with an array of competing and often contradictory customs, the judiciary established the parameters of what constituted judicially recognized, and therefore state-sanctioned, “tradition.”

The judicial establishment of tradition was followed by its codification by the colonial executive, such as in the Hindu and Muslim law code bills, which created corpuses of standard communal private law. These traditions thus transformed into central tenets of exclusivist communal identities, which in turn became politicized through their patronage by the colonial state. Rather than the state enforcement of uniformity, so often central to the construction of the modern state, colonial authorities codified and enforced difference.

The Raj reinforced this difference through the categorization of its subjects in the decennial census, where it denominated people into religiously based communities to which it then dispensed entitlements. The most important manifestation of this communally centered politics in the formal, state-regulated arena was the creation and extension of separate electorates. Muslims, Christians, and Anglo-Indians were granted separate electoral lists in which candidates and eligible voters were restricted to members of these denominated communities. The Morley-Minto reforms of 1909 first made widespread use of separate electorates, which were significantly extended by the Montague-Chelmsford reforms of 1919 and the 1935 Act on the basis of the 1932 Communal Award. GoI leaders’ official rationale for the use of separate electorates was twofold. First, they sought to deny Indian nationalists an outright majority in the formal structures of government, which they feared open elections would ensure them. Second, the Government believed that by granting Muslims separate electorates where they would be electoral minorities in all but two of the provinces of British India (Bengal and the Punjab) they would be forced to look to the Raj as their protector, thus more firmly tying Muslim fortunes to those of the British. The British believed that because separate electorates would fracture the formal spaces of governance they surrendered to Indians, native politicians would be forced to work on the basis of cross-communal alliances. This course would therefore have a moderating influence on communal politics, which would reward the collaborative, conservative elites on whom British authority largely depended.

The colonial state’s enumeration of people along confessional lines was only one of the ways in which it categorized people. It also enumerated people according to their caste affiliation, specifying their varna as well as jati. The colonial state used these categories to create communal rights and entitlements as well as to facilitate communal punishments. Untouchables, also known as “backward” or “scheduled caste,” mainly suffered social discrimination widespread throughout the subcontinent, while the “criminal tribes” were the objects of penal state regulation. Whereas the separate enumeration of the former by the Raj was partly an attempt to ameliorate their low social position through special state dispensation, the latter was purely a punitive construction of the colonial state creating categories of “group” criminality. Yet the consequences of categorization varied widely throughout India, with members of the “same” community experiencing differential treatment in the various regions of British India as well as in the princely states. The legal positions of both the untouchables and tribes were transformed.
with the advent of independence, when these groups were granted comparatively extensive political entitlements and reservations. The use of communal patronage and punishment as a strategy of governance imprinted a lasting legacy on Indian politics.

By the end of the First World War, British governing circles reached a consensus that India would eventually have to be granted independence. However, no time line for such a move was agreed upon. Their actions during the interwar period were designed to more firmly embed British rule. The Raj endeavored to undermine the appeal of all-Indian nationalists through the inclusion of Indian elites in local elected assemblies. Yet as the GoI invested localities with governmental responsibilities, it tightened its grip on key areas of governance it considered essential to its paramountcy—defense, communications, and foreign affairs. The British sought to fracture Indian political opinion further through the use and extension of separate electorates for “minorities” within the newly elected assemblies. By channeling state-recognized political power through communal identity, separate electorates had dire consequences for the Indian body politic.

By 1945 the once far-off potentiality of Indian independence had become an imminent reality. The cost of the Second World War, Britain’s early defeats by the Japanese, and the force of Indian nationalism combined to shatter the myth of the Raj’s invincibility. The most extreme anti-British nationalists found expression during the war under the leadership of Subhas Chandra Bose, former president of the Congress, in his Indian National Army (INA) set up under the tutelage and ultimate control of the Japanese. The campaigns against the Japanese and their INA auxiliaries in Burma from 1942 onward had a lasting psychological effect on the Raj. More powerfully however, the activities of mainstream Indian nationalists, culminating in the Quit India movement of 1942, underlined the Raj’s moral and political bankruptcy and also laid bare the costs and limits of what force could achieve. The memory of the wartime experiences of Indian nationalism weighed heavily on the minds of British policy makers as they looked to their future in the subcontinent, forcing an acknowledgment that the local collaborationist politics that had been the foundation of authority during the interwar period no longer served the realities of a postwar world. Opting for a quick exit, the British negotiated the transfer of power with India’s nationalist politicians, represented by Congress and the All-India Muslim League. Congress, proponent of a strong center, jockeyed with the League, which claimed to exclusively represent India’s Muslims and advocated a federal outcome, to author India’s independent future. Under pressure to leave and recognizing the League’s weakness, the British decided on Congress. Their withdrawal led to the independence and partition of the Indian subcontinent into the successor states of Pakistan and India. Partition was accompanied by horrendous communal violence and resulted in the largest forced migration in recorded history. After nearly two hundred years, the Raj succumbed to a bloody and ignominious end.

In the early twenty-first century the memory of the Raj remains contested. In the immediate aftermath of independence, nationalists attempted to minimize the legacy of the Raj and largely expunge it as a historical aberration in the Subcontinent’s history. A nationalist tradition of historiography buttressed popular perceptions of the Raj as an episode of exploitation that was eventually defeated by the strength of the Indian freedom struggle. This image remains firmly fixed in the public imaginations not only of India and Pakistan but also to a significant extent of Britain as well. Nostalgia for the Raj, however, has continued to be a subtle but powerful countercurrent. The belief in the ultimate munificence of the Raj, held by a few intransigent imperialists and their collaborators, has morphed into a more muted romantic reminiscence. The experience of rule is projected through the memory of those who wielded authority, such as the families of imperial administrators, as days of order, innocence, and benevolence. The juxtaposition of “Raj nostalgia” with a narrative nationalist “freedom struggle” underlines the depth of the experience linking South Asia and Britain. Just as the experience of the Raj had a diverse array of expressions, so too does its memory.

B. D. Hopkins
The random effects and random-effects models differ in their interpretations of the \( v_i \) term: In the fixed-effects model, the \( v_i \)s are treated as fixed parameters (unit-specific \( y \)-intercepts); in the random-effects model, in contrast, they are treated as random drawings from a given probability distribution.

In the fixed-effects approach, we merely acknowledge that differences between individuals exist. Therefore, the parameter \( \beta \) can be estimated by including a dummy variable for each cross-sectional unit and suppressing the global constant. If, however, we are willing to go the extra step of modeling the \( v_i \), greater efficiency may be attained by using Generalized Least Squares (GLS), taking into account the structure of the error term. This is the random effects approach (for an early and influential example of this, see Balestra and Nerlove 1966).

Consider observations on a given unit \( i \) at two times \( s \) and \( t \). From the hypotheses above, it follows that \( \text{Var}(u_{it}) = \text{Var}(u_{ij}) = \sigma^2_v + \sigma^2_u \), whereas between \( u_{it} \) and \( u_{ij} \) is \( \text{E}(u_{it}, u_{ij}) = \sigma^2_u \). In matrix notation, we may group the \( T_i \) observations for unit \( i \) into the vector \( y_i \) and write

\[
y_i = X_i \beta + u_i,
\]

The vector \( u_i \), which includes all the disturbances for \( i \), has covariance matrix

\[
\text{Var}(u_i) = \sum_j = \sigma^2_v + \sigma^2_u J
\]

where \( J \) is a square matrix with all elements equal to 1. It can be shown that the matrix

\[
K_i = I - \frac{\theta}{T_i} J,
\]

where \( \theta = 1 - \frac{\sigma^2_u}{\sigma^2_v + T_i \sigma^2_u} \) has the property

\[
K_i^2 \Sigma K_i = \sigma^2_v I
\]

It follows that the transformed system

\[
K_i y_i = K_i X \beta + K_i u_i
\]

satisfies the Gauss-Markov conditions, and OLS estimation of (5) provides efficient inference. But because

\[
K_i y_i = y_i - \theta \hat{y}_i
\]

GLS estimation is equivalent to OLS using “quasideemeaned” data—that is, variables from which we subtract a fraction \( \theta \) of their average. Notice that for \( \sigma^2_v \to 0, \theta \to 1 \), whereas for \( \sigma^2_u \to 0, \theta \to 0 \). If all the variance is attributable to the individual effects, the fixed-effects estimator is optimal; if, instead, individual effects are negligible, then pooled OLS is optimal.
To implement GLS we need to calculate $\theta$, which in turn requires estimates of the variances $\sigma_\varepsilon^2$ and $\sigma_v^2$. (These are often referred to as the “within” and “between” variances, respectively, because the former refers to variation within each cross-sectional unit and the latter to variation between the units). Several means of estimating these magnitudes have been suggested in the literature (see Baltagi 2005).

The above derivation presupposes that the $\varepsilon_{it}$ term is IID. Departures from this assumption (e.g., heteroskedasticity) have been analyzed, leading to a sizable body of literature (see, for example, Baltagi 2005 and Arellano 2003).

When is the random effects estimator preferable to fixed effects? If the panel comprises observations on a fixed and relatively small set of units of interest (for example, the member states of the European Union), there is a presumption in favor of fixed effects, because it makes little sense to consider the $v_i$ terms as sampled from an underlying population: In the case of the European Union states, the sample and the population coincide, and even a thought experiment in which the units are different would be audacious. If, instead, the sample comprises observations on a large number of randomly selected individuals (as in many epidemiological and other longitudinal studies), there is a presumption in favor of random effects. Besides this general heuristic, however, certain statistical issues must be taken into account.

First, some panel data sets contain variables whose values are specific to the cross-sectional unit but which do not vary over time (for example, the gender of an individual). If such variables are to be included in the model, the fixed-effects option is simply not available. (When the fixed-effects model is implemented using the dummy variables approach, the trouble is that any time-invariant variables are perfectly collinear with the unit dummies.) Second, the random-effects estimator can be shown to be a matrix-weighted average of pooled OLS and the “between” estimator (a regression using the group means, and hence ignoring the intragroup variation). Suppose we have observations on $m$ units and there are $k$ independent variables of interest. If $k > m$, the “between” estimator is undefined—we have only $m$ effective observations—and hence so is the random-effects estimator.

If one does not fall foul of one or other of these issues, the choice between fixed effects and random effects may be expressed as a tradeoff between robustness and efficiency.

The robustness of the fixed-effects approach stems from the fact that it makes no hypotheses regarding the differences in mean across the units, except that such differences exist. This estimator “always works,” but at the cost of not being able to estimate the effect of time-invariant regressors.

The richer hypothesis set of the random-effects estimator allows for estimation of the parameters for time-invariant regressors, and ensures that estimation of the parameters for time-varying regressors is performed more efficiently. But these advantages are tied to the validity of the additional hypotheses. If the individual effects are correlated with some of the explanatory variables, then the random-effects estimator is inconsistent, whereas fixed-effects estimates are still valid. It is on this principle that the “Hausman test” (Hausman 1978) is built: If the fixed-and random-effects estimates agree, to within the usual statistical margin of error, then there is no reason to believe the additional hypotheses are invalid, and as a consequence, no reason not to use the more efficient random-effects estimator.

RANDOM SAMPLES

A teacher has four students who have done well in their homework, and she wants to reward them by assigning them a special task that they enjoy. The problem is that the task requires only two students. What is a “fair” way to choose the two students who receive the reward? When this question is posed to the students themselves, they are quite likely to say something like, “Put the four names on individual slips of paper in a box, mix them up, and have someone draw out two names, sight unseen.”

The students are describing a random sample of two names from the four. Labeling the names as $A, B, C,$ and $D$, the six possible samples of size two are $(A,B), (A,C), (A,D), (B,C), (B,D),$ and $(C,D)$. Because there is no reason to suspect that one sample is any more likely than another, the appropriate probability model for this ran-
Random sampling assigns each of the six a probability of 1/6. This leads to a definition of a simple random sample for the general case in which \( n \) names are selected from the \( N \) names in the box, generally called the population. A simple random sample of \( n \) objects selected from a population of \( N \) distinct objects is a sample chosen so that all possible samples of size \( n \) have an equal chance of being selected.

It follows from basic rules of probability that the probability that person \( A \) gets selected, written \( P(A) \), is given by \( P(A) = 1/2 \); because three of the six equally likely samples have \( A \) in them. For the general case, the probability of any one object ending up in the sample is \( n/N \). Thus the definition implies that, in simple random sampling, each individual has the same chance of being selected as any other individual. The reverse statement is not true, however. A method of sampling that gives each individual the same chance of being selected is not necessarily a simple random sample. For example, suppose \( A \) and \( B \) are male and \( C \) and \( D \) are female. Then selecting one male at random and one female at random gives each person the same chance (1/2) of being selected, but no sample would ever contain two boys or two girls.

If \( N \) and \( n \) were large, the process of physically drawing names from a box would be impractical if not impossible. Most often simple random samples are selected by a process that essentially numbers each of the \( N \) objects and then generates \( n \) random numbers between 1 and \( N \) by means of a calculator or computer, selecting as the sample those objects whose numbers were so generated.

**SAMPLING WITHOUT AND WITH REPLACEMENT**

The sampling scheme described above is referred to as sampling without replacement. Drawing the two names is mathematically the same as drawing one name at random and then drawing a second name from those that remain in the box. Using basic rules of probability, it follows that

\[
P(\text{selecting } A \text{ and then selecting } B) = P(A \text{ on first draw}) \cdot P(B \text{ on second draw given that } A \text{ is already selected})
\]

\[
= (1/4)(1/3) = 1/12.
\]

To get the probability of the sample \((A,B)\) this has to be doubled, because \( B \) could have been selected first and \( A \) second. Thus \( P(A,B) = 1/6 \), as shown above.

Suppose, however, that the two students receiving the reward could perform the task separately and at different times, so the same person could be selected twice. This could be accomplished by selecting one name at random, placing that name back in the box, and selecting the second name at random from the same set of four names. Under this scheme of sampling with replacement,

\[
P(\text{selecting } A \text{ and then selecting } B) = P(A \text{ on first draw}) \cdot P(B \text{ on second draw given that } A \text{ is already selected})
\]

\[
= (1/4)(1/4) = 1/16.
\]

Because the probability of selecting \( B \) after \( A \) is the same as the probability of selecting \( B \) on the first draw, the events “select \( A \)” and “select \( B \)” are said to be independent. Under independence (sampling with replacement), the probability of selecting two specific students changed from that of sampling without replacement. Suppose, however, that \( N \) were 40,000 instead of 4. Then removing one object would not appreciably change the probability on the second draw, and the counterparts of the two probabilities displayed above would be practically equal.

This fact leads to a second definition of a random sample, one based on independence. A random sample of size \( n \) is a set of \( n \) objects selected independently and at random from the same set of \( N \) objects.

If \( N \) is large compared to \( n \), the second definition results in a probability structure for the sample that is approximately the same as that of the first definition. Moreover the second definition makes the statistical theory of sampling much easier to work out. That fact, coupled with the fact that the most common uses of random sampling, sample surveys and opinion polls generally involve large populations, makes the second definition more useful in practice.

Populations have been discussed thus far as if they were well-defined entities that the sampler could actually see or list. Consider a classical die toss using a balanced die. The population of possible outcomes of die tosses is infinite and conceptual, but it can readily be modeled as if the possible outcomes, 1 through 6, were represented in equal numbers because it seems logical to think of each possible outcome as having probability 1/6. Using the second definition then, a set of \( n \) outcomes generated from independent tosses of a balanced die can be considered as a random sample, each outcome being randomly (through the tossing) and independently (assuming the second toss is not influenced by the first) selected from this large, conceptual population.

**RANDOM SAMPLING AND STATISTICAL INFERENCE**

Random sampling forms the probabilistic basis for statistical inference. Consider the common opinion poll in which \( n \) people are randomly sampled from a large population of \( N \) people. Because \( N \) is usually large, the inde-
The independence model provides a good approximation, even though the samples are selected without replacement. The goal of such a poll is to estimate a population proportion, $p$, such as the proportion of voters that favor a certain candidate. The estimate of $p$ is the corresponding sample proportion, often designated by $\hat{p}$, of voters in the sample who favor the candidate. Due to the random sampling and the mathematics of probability, many facts can be established with regard to $\hat{p}$. If $n$ is large, $\hat{p}$ has a small chance of being "far" from the true $p$ it is estimating. In fact $\hat{p}$ will be within a distance of approximately $1/\sqrt{n}$ from $p$ about 95 percent of the time in repeated sampling. (This is why a poll of 1,000 persons is said to have a margin of error of about 3 percent.) If a poll is done many times, it will give results close to $p$ most of the time but can miss by a large amount on occasion (about 5 percent of the time).

The facts stated above are related the result that the values of $\hat{p}$ will have an approximately normal distribution (mound-shaped symmetric distribution) when random samples of the same size are taken repeatedly from the same population. The figure below shows a simulated distribution of 200 $\hat{p}$ values for samples of size 50 taken for a population with $p = 0.40$. The theoretical margin of error is approximately $1/\sqrt{50} = 0.14$, indicating that a $\hat{p}$ of 0.54 or more would be an extremely rare occurrence. Such an outcome occurred only 7 times out of 200 in this simulation (see figure 1).

### THEORY VERSUS PRACTICE

All of the above presents a neat theory of random sampling, but obtaining a truly random sample in practice is nearly impossible for most sampling situations. Consider the relatively simple situation of selecting a sample of students from a college. First, the population to be sampled needs a clear definition (but what constitutes a student?). Second, a list of students will be needed (but this changes almost every day). Third, even with a good definition and a good list, the sampled students may not be able to be found or, if found, may not be willing to respond (or respond correctly) to a survey. These three concerns, population definition, population dynamics, and nonresponse, cover many of the practical difficulties that occur in nearly all sampling problems. They are compounded with others in surveys of subjects who are hard to find anyway, such as victims of war atrocities. In many situations the difficulties can be mitigated by a more complex sampling design, the most common features of which involve stratification (divide the population into nonoverlapping but relatively large groups and take a random sample from each) and clustering (divide the population into many relatively small nonoverlapping groups and take a random sample of the groups). A national survey that selects respondents by state is an example of stratification. A city survey that samples city blocks, rather than households, and then interviews someone in each household in every sampled block is an example of clustering.

### RANDOM WALK

A random walk is one in which future steps or directions cannot be predicted on the basis of past actions. When the term is applied to the stock market, it means that short-run changes in stock prices cannot be predicted: Investment advisory services, earnings predictions, and complicated chart patterns are useless to the investor.
ORIGINS AND RATIONALES
The application of the random walk hypothesis to stock prices usually is associated with Samuelson (1965), although the general idea that security prices change randomly goes back at least to the time of Bachelier (1900). The basic rationale for the hypothesis is that securities markets are very efficient at digesting information. When information arises about a particular security or about the market in general, the news spreads quickly and is incorporated into the price of that security without delay. Armies of investment managers pounce on any news that could affect the value of a security. By their trading, they ensure that security prices fully reflect all available information. As a result it is not possible to make profitable trades on the basis of that information because any potential profit will have been realized already. Changes in the prices of securities will be random and unpredictable.

The random walk hypothesis does not imply that movements in security prices are erratic or capricious. However, tomorrow’s price change in securities markets will reflect only tomorrow’s “news” and will be independent of the price change today. True news by definition is unpredictable, and thus the resulting price change also must be unpredictable and random.

The term random walk usually is used loosely in the finance literature to characterize a price series in which all subsequent price changes represent random departures from previous prices. Thus, changes in price essentially are not related to past price changes. It is believed that the term was used first in an exchange of correspondence in Nature in 1905. The subject was the optimal search procedure for finding a drunk who had been left in the middle of a field. The solution was simply to start where the drunk had been left. That point provides the best unbiased estimate of the drunk's future position because presumably he will have staggered along in an unpredictable and random fashion.

If stock price movements approximate those of a random walk, technical analysis (the making and interpretation of stock charts to divine the future) is unlikely to offer investors a guide to making above-average profits. Moreover, trading strategies that seek to buy and sell stocks on the basis of charting signals will not help investors outperform a simple buy-and-hold strategy.

Considerable statistical work has supported the random walk hypothesis. Changes in stock prices from day to day are essentially uncorrelated, and news seems to be reflected in the prices of securities without delay. Although markets sometimes overreact to news, they underreact at other times. Several technical trading systems have been tested, and they do not produce greater profits after transactions costs than does a simple buy-and-hold strategy.

The stock market does not fully meet all the conditions for a random walk, however. Some slight dependencies have been found, and there is a small degree of momentum in stock prices. Some seasonal patterns have been discovered. However, the dependencies that have been found are very small relative to the transactions costs that would be required to exploit them, and they are not dependable from period to period.

Logic suggests that any patterns that might have existed in the past are likely to self-destruct in the future. Suppose, for example, there was a dependable Christmas rally; that is, the stock market consistently rose in the trading days between Christmas and New Year's Day. Traders attempting to profit from that pattern would plan to buy the day before Christmas and sell the day before New Year's Day. However, pre-Christmas buying would make stock prices rise the day before Christmas and fall the day before New Year's as traders unloaded their positions to realize profits. Hence, to beat the gun, traders would have to buy two days before Christmas and sell two days before New Year's Day. Before long all the buying would take place before Christmas and the selling would occur after Christmas, and the year-end rally would disappear. Any dependable pattern that could be exploited for profit would self-destruct. This is the logical reason why dependable patterns in stock prices are unlikely to persist.

IMPLICATIONS FOR INVESTORS
The random walk hypothesis has important implications for investors in the stock market. Visually, charts of stock prices appear to display some obvious patterns, but those patterns are simply a manifestation of a statistical illusion. The “cycles” in stock charts are no more true cycles than are the runs of luck or misfortunes of the ordinary gambler. History tends to repeat itself best in an infinitely surprising variety of ways that confound any attempts to profit from knowledge of past price patterns. Although the market does not meet the statistician’s ideal of a perfect random walk, any systematic relationships that exist are so small and undependable that they are not useful for an investor. The history of stock price movements contains no useful information that will enable an investor consistently to outperform a buy-and-hold strategy in managing a portfolio.

Attempting to use past patterns of stock prices to ascertain the times when investors should be out of the market is especially dangerous. Because there is a long-term uptrend in the stock market, it can be very risky to be in cash. An investor who frequently carries a large cash position to avoid periods of market decline is very likely to be out of the market during some periods when it rallies smartly. Market timers risk missing the infrequent big gains that are the main contributors to performance, and
they also pay more in taxes and transactions costs than does an investor who simply buys and holds a diversified portfolio.

RANDOMNESS
Randomness is a term used in the social sciences and mathematics to refer to chance factors occurring in a manner that the individual events in a series of events or outcomes do not exhibit a connection to each other in their occurrence. Events are independent of each other, and thus the occurrence of one event is not linked to the occurrence of other events in a series in any systematic manner.

Randomness as a quality of a series of events is believed to be the result of numerous minor causes producing small effects as an outcome that results in no systematic predictability for a given event in the series. The result of the many small causes, some canceling each other, is the independence of each event from the others. It is notable that the operation of causation is not denied in the universe of events and experiences. Rather, the causal background to a series of random events is interpreted as a multiplicity of small influences, some almost infinitesimal in impact, with some causes canceling or partially canceling the influence of other causes. The outcome is a series of events with independent occurrence in relation to each other. The word chance is used in popular speech to refer to this condition wherein events are generated independently of each other.

RANDOMNESS AND RANDOM DISTRIBUTIONS
Of great interest to social scientists is the demonstrable fact that some random distributions follow broadly predictable patterns when a series of events occurs in large numbers. Individual outcomes or instances cannot be predicted with any certainty, but a random pattern may be demonstrated to follow a broad configuration in such a manner that larger areas in the distribution of random events may be assigned a broad likelihood or probability of occurrence. Examples include various known or empirical distributions of random events that follow the bilaterally symmetrical distribution that forms a curve known as the normal curve. Another related known probability distribution is the binomial distribution, where only two possible outcomes can occur in a random series of events, such as tossing an unweighted coin a large or an even infinite number of times. The binomial distribution approximates the normal curve of probability with a large series of discrete, independent trials of two possible outcomes. Yet another known distribution of random events is the chi-square distribution when the \( \chi^2 \) statistic is calculated on a number of randomly drawn samples if the samples themselves are drawn from a larger universe of randomly distributed frequencies for a number of categories of observations. The tables that summarize the patterns of these known distributions of statistics are available in any book on statistical method.

STATISTICS AND RANDOMNESS
The field of statistics as it is applied in research in the social sciences can be broken into two broad divisions: descriptive statistics and inferential statistics. The purpose of the first division, descriptive statistics, is the summary of data. Data are ordinarily summarized by measures of central tendency, such as means, medians, and the mode. Variation or dispersion of data can be summarized with measures of variance and standard deviations. If there are two or more variables measured, a researcher may search for association through measures of correlation.

The second broad division in statistics is inferential statistics. This is the division used to deal with randomness and the use of known random distributions to compare for departures from randomness in empirical distributions. Departures from randomness in the latter situation can be assessed probabilistically and can be of great value in the assessment of causation. The search for causation begins with the determination by an observer of correlation or association between observations. Departures from randomness are of great importance because there is an initial indication of a pattern of association or correlation.

This second broad area of inferential statistics is itself broken into two large divisions. The first division involves estimation of parameters or universe values. This is attempted when a smaller sample must be drawn from a larger population or universe. The value calculated on
Rape

A sample is referred to as a statistic. A mean calculated for a sample is a statistic. If the mean were calculated for an entire population, it would be referred to as the parameter. Researchers are often required to estimate parameters based on sample statistics due to limitations in time, personnel, and particularly the cost of conducting research on an entire population. Randomness is an important consideration for estimation of parameters because a sample must be drawn through a random process if an inference is to be made as a probability statement for the parameter value.

This requirement exists because the estimation of the parameter, or population mean, is based on knowledge of the pattern of a series of randomly sampled means, or a sampling distribution of means. This known sampling distribution approximates a normal curve, with the latter’s known probabilities for areas under the curve. Random sampling matches the assumptions of randomness for the pattern of means in the sampling distribution and thus enables a researcher to calculate the probability of being in error while using a sample mean to estimate the parameter of the population.

A second division of inferential statistics involves prescribed procedures used in hypotheses testing. Hypotheses testing is used in research as a search for the existence of relationships in a population or larger universe of possible observations. Again, random samples must be used if exact statements of probability are to be made in regard to the hypotheses being tested. Research scholars vary in style of work, but a typical model utilizing randomness is one that searches for non-randomness or hypothesized correlated variables by generating research hypotheses of correlation between categories of empirical observations or variables and then tests for these correlations through statistical procedures, such as a difference of means test, chi-square, or tests of significance for randomly sampled measures that yield the sampled correlation coefficients.

In this manner of conducting research, the hypothesis of randomness, or no relationship, which is referred to as the null hypothesis, is cast against a set of empirical frequencies drawn from a random sample. If the test of differences between means, or the $X^2$ statistic, or the sampled correlation coefficients yield a value or values that are so large that they are unlikely to occur by chance in repeated random samples from random distributions with their known statistical patterns, inferences can be made regarding the likelihood of a correlation or relationship between the hypothesized variables in the larger universe from which the samples have been randomly selected. This family of tests is known as significance tests. Thus the observation and understanding of random events enables one to become knowledgeable about random patterns. This knowledge of random patterns is useful for social scientists as it enables them to make inferences about causes in the social world, which is largely a non-random world, and thereby to build theoretical explanations based on empirical research to reach a better understanding of the complex social world in its many structured variations.

RAPE

Rape is a crime of sexual coercion that can cause acute physical and psychological trauma. Its victims are mostly female, although males may be rape victims as well. Nearly all rape perpetrators are male.

PREVALENCE AND EFFECTS

Research conducted in the United States provides a window on the prevalence of rape. Approximately 20 percent of American women report that at some point in their lives they have been forced to have sexual intercourse against their will. Approximately 8 percent of American females indicate that their first experience of sexual intercourse was coerced. Although legal and cultural climates surrounding the crime of rape vary greatly around the globe, research suggests that rape is a widespread phenomenon and that most rapes go undetected. Mass rape has also been used as a weapon of warfare, torture, and genocide—notorious in the 1990s and early 2000s in Bosnia, Rwanda, and Darfur—and has been classified under international law as a crime against humanity. Rape in U.S. prisons is a significant problem that remains largely unaddressed.

Victims of rape report an experience of degradation, often with immediate effects of physical paralysis and...
mental dissociation. Studies indicate that victims of acquaintance rape can suffer as much or more psychological harm than victims of stranger rape, in part because they experience more intense feelings of guilt and self-blame. Almost one-third of rape victims experience fragmented memory, traumatic amnesia, or other long-term effects, similar to those associated with posttraumatic stress disorder. These common symptoms of sexual trauma can compromise the victim’s ability to report the crime in a coherent narrative and to demonstrate nonconsent for a legal proceeding.

DEFINITION AND PUNISHMENT
Historically, the law defined rape as a man having sexual intercourse with a woman through the use of force and without her consent. In his leading legal treatise of the eighteenth century, Commentaries on the Laws of England (1765), William Blackstone (1723–1780) described rape as “carnal knowledge of a woman forcibly and against her will” (p. 209). This definition remained remarkably static for generations.

In contemporary law, force and consent became irrelevant in statutory rape, which presumes involuntary any sexual relations with a person under an age specified by statute. First enacted into law in England in 1275, statutory rape laws are common in the United States but rarely enforced against consensual sexual relationships between adolescents. The rare statutory rape prosecution is likely to involve an older man and an underage woman, and some jurisdictions have statutes that require the perpetrator to be over twenty-one or significantly older than the victim. Originally the age of consent for statutory rape was twelve, later reduced to ten. Although the nineteenth-century women’s movement successfully lobbied to raise the age limit for statutory rape, in some states the age limit remains as low as thirteen. Other states consider sixteen or eighteen to be the appropriate age of consent.

In early England, rape was classified as a misdemeanor to be punished by a fine or imprisonment. By virtue of a statute enacted in 1285, rape became a capital felony, a classification imported to colonial America. During the twentieth century, however, imprisonment became the most common punishment for rape convictions.

PROPERTY AND RACE
From the seventeenth through the nineteenth century, notions of property shaped the understanding of rape. Female slaves, deemed the property of their owners, could not be raped under law and therefore received no protection from rape law. In situations where rape law applied, rape was understood as a crime of trespass committed by a male stranger against the property of another man, the husband or father of the woman who was raped. Hence, rape within marriage was considered legally impossible. Even after America’s formal abandonment of the notion of women as property, its influence reached into the twentieth century through the marital exemption from rape laws that continued to presume a wife’s consent to all intercourse with her husband, even when it was coerced. Although all states have abolished the full marital rape exemption, some still retain it in partial forms.

From the eighteenth through the mid-twentieth century, rape indictments and conviction rates in America were low, except when defendants were nonwhite. African American men alleged to have raped white women were zealously prosecuted, even in cases where there was reason to doubt the allegation’s reliability. About 90 percent of the men executed for rape in the twentieth century in the United States were African Americans. This racialized pattern of punishment was noted by the U.S. Supreme Court in the 1977 case of Coker v. Georgia, which held the death penalty for rape to be unconstitutional.

In marked contrast, when victims were African American women, rape laws were largely unenforced, especially during the slavery era. Rape of female slaves, which could reproduce more slave labor for the owner’s service, was a commonplace occurrence. Studies suggest that African American women who report being raped continue to have disproportionate difficulties obtaining redress through the legal system, as their reports are especially likely to be regarded with suspicion.

REFORM EFFORTS
For centuries a culture of skepticism surrounded all women’s accusations of rape. Such skepticism is revealed in the language of the seventeenth-century English jurist Matthew Hale (1609–1676) in his History of the Pleas of the Crown (1847): “It must be remembered, that [rape] is an accusation easily to be made and hard to be proved, and harder to be defended by the party accused, tho never so innocent” (p. 635). Such an attitude is also apparent in the law’s traditional requirements that proof of rape entailed not only evidence of the use or threatened use of force but also evidence of resistance—resistance to the utmost of the victim’s physical capacities in some states—as a proxy for nonconsent. Additionally, some jurisdictions required corroboration of a victim’s testimony and cautioned jurors to give it extra scrutiny. Most of these procedural hurdles have formally disappeared in the United States, although some, such as corroboration requirements, remain in other legal systems around the world.

The first twentieth-century effort to modernize rape law in the United States came with the 1950s revision of the Model Penal Code (MPC), an influential model statute written by recognized legal experts. According to
the MPC, rape victims no longer needed to resist “to the utmost” to demonstrate nonconsent. This revision led many states to abolish resistance requirements. The MPC also proposed three grades of sexual assault. Violent stranger rape was felony rape in the first degree. Violent acquaintance rape was a second-degree felony. Other kinds of sexual coercion established the third-degree felony of “gross sexual imposition.” Adapting this approach, many states adopted statutory schemes that graded rape offenses by severity.

Rape law reform continued in the 1970s and 1980s when feminist reformers raised awareness of the extent of the incidence and harm of rape and the law’s failure, despite harsh potential penalties, to hold most perpetrators accountable. In her book Real Rape: How the Legal System Victimizes Women Who Say No (1987), law professor Susan Estrich observed that date rapes or acquaintance rapes are the most common kinds of rape, yet the criminal justice system is less likely to treat these cases as crimes and may even blame the victims for the incidents. Victims experience dehumanization from all of these rapes, all of them violate a victim’s bodily integrity and sexual autonomy, but only victims of violent stranger rape are likely to have recourse to the legal system.

Some proposed reforms have received widespread acceptance. For example, along with the broad elimination of resistance and corroboration requirements, rape shield laws that, with some exceptions, prohibit admission of the victim’s prior sexual conduct have been widely adopted. Studies, however, are inconclusive as to whether these reforms have made a measurable difference in victim behavior or case outcomes.

Other proposed reforms remain controversial, such as whether sex obtained through fraud or extortion can constitute rape. Another area of controversy concerns whether and under what circumstances to allow mistakes about the consent to establish a defense to rape. Estrich’s book sparked a “no-means-no” movement, advocating verbal resistance as sufficient to establish nonconsent. Others have suggested that the absence of affirmative assent or of a verbal discussion about desired acts should undermine consent as a defense in rape cases. Strong arguments have been made to abandon force as an element of rape, because the use of force is inherent in unwanted sex. New Jersey did so in the case of In re M.T.S. (1992), and some state statutes classify nonconsensual penetration without force as a sexual offense, although typically one less serious than rape.

While reform efforts have been influential in drawing attention to a variety of problems in social and legal responses to rape, popular attitudes are harder to modify than written laws. Solving many of these problems will require deeper cultural change.

#### RASTAFARI

Following the 1930 crowning of Ras Tafari (1892–1975) as Haile Selassie (“Power of the Trinity”), Emperor of Ethiopia, several street-corner preachers in Jamaica (among them, Joseph Hibbert, Leonard P. Howell, Robert Hinds, Archibald Dunkley, and Paul Earlington) began asserting that Selassie was a divine personage or the reincarnated Christ. For these Jamaicans, Selassie embodied Marcus Garvey’s vision of black pride, self-reliance, and...
repatriation to Africa; signaled the restoration of Ethiopia's ancient glory; and fulfilled the Bible's prophecies of a messianic deliverer. In proclaiming Selassie a messianic figure, they pinned on him their longing for liberation from the legacy of slavery and colonialism.

From the activities of these founding personalities there emerged a set of religious, social, and political beliefs known as Rastafari (or Rastafarianism), the adherents of which are termed Rastas (or Rastafarians). From its beginning, Rastafari represented a fundamental critique of the values and institutions of Jamaican society. Rastas' declaration of adherence to a black messiah indicated their rejection of both European religion and the authority of the colonial state. By referring to Jamaica as Babylon—land of exile, oppression, and exploitation—they expressed their conviction that this was a society with no redeemable values or institutions, and declared their intention to repatriate to their African homeland, from which they had been "stolen." The Rastas' explicit promulgation of black superiority—admittedly, an overcompensation for centuries of denigration—signaled not just a rejection of the ideology of white supremacy, but even more a reclamation of blackness and of Africa.

From the 1930s to the 1960s, conflict characterized the relationship between Rastafari and Jamaican civil authorities. The charismatic Rastafarian leader Leonard P. Howell exemplified this conflict in the early decades. For inveighing against the British colonial government, he was repeatedly arrested and imprisoned. Law enforcement also repeatedly raided Pinnacle—the commune he established—and eventually demolished it in 1954. The authorities concluded that Howell was demented and committed him to a mental institution. After his release, Howell lived in relative obscurity until his death in the mid-1980s.

By the late 1940s or early 1950s, the House of Youth Black Faith (HYBF) had emerged as the avant-garde of the Rastafari movement. These young Rastas were even more radical than their elders. They elevated the smoking of ganja (marijuana) to a personal and communal ritual, which they believed aided them in the discovery of their spiritual and cultural identity by breaking through the mental confines imposed by Babylon. They adopted the dreadlocks hairstyle to accentuate their Africanness and to symbolize their rejection of European standards of beauty (favoring fine, straight hair). They are also credited with the development of dreadtalk, an argot that made their speech often unintelligible to outsiders. Furthermore, HYBF projected an aura of militancy through marches and street meetings, vitriolic language calling down “blood and fire” on Babylon and its agents, and the flaunting of laws against ganja possession and use.

For their marijuana use, dreadlocks hairstyle, and general insubordination, Rastas became subjected to the ire of the agents of social control and public opinion: They suffered frequent arrests on drug charges, scapegoating that saw them blamed for a range of criminal activities, and characterizations in the media as lazy, demented, and disposed to violence. When a few weapons were found in the compound of Claudius Henry, a Rastafarian elder, and when his son was implicated in an alleged plot against the Jamaican government, the repression escalated into indiscriminate harassment, arrests, and forced cutting of the locks of Rastas.

Though a 1960 study of Rastafari by University of the West Indies professors M. G. Smith, Roy Augier, and Rex Nettleford effectively debunked myths about the mental deficiency, laziness, and criminality of Rastas, negative views of Rastafari persisted. These prejudices reached a boiling point in 1965, when an attempt to keep Rastas out of the area surrounding the Rose Hall Great House (a tourist attraction) escalated into a virtual riot in which several people were killed. When the government found “evidence” of the endemic criminality of a West Kingston slum in the mid-1960s, Rastas again took the rap. In an attempt to deal with what it considered entrenched Rastafarian criminality, the government bulldozed the entire shantytown where Rastas and others had constructed shacks on an urban dump.

Though a negative perception of Rastafari persisted among many in Jamaican society after 1960, the Smith, Augier, and Nettleford study helped to influence Jamaica's political leadership to adopt a less confrontational approach to the Rastafarian phenomenon. In 1961 Norman Manley's People National Party (PNP) government sent a delegation of civic leaders and Rastas to West Africa and Ethiopia to determine which African countries would be willing to receive Jamaicans desiring to return to the continent of their ancestors. The official report indicated that these countries were only willing to welcome educated and skilled workers. The Rastas of the delegation issued their own report, however, painting a picture of African countries waiting to receive their diasporic children with open arms. Jamaica gained its independence in 1962 under a new Jamaican Labor Party (JLP) government that was less disposed to pursue repatriation for Rastas. Though some Rastas formed their own delegation to make another trip to Africa in 1963, no official repatriation ever took place.

Another measure growing out of the 1960 study was a concerted effort by the Jamaican government to establish cultural and political ties with African countries. This included an invitation to the Ethiopian Orthodox Church to establish itself in Jamaica, and an exchange of visits by Jamaican and African dignitaries. The Ethiopian
Orthodox Church eventually established a congregation in Kingston in 1970, and has established further congregations in several other towns since then. Many Rastas identify with or have become members of this church, but they have often come into conflict with its orthodox teachings. The visitor exchange culminated with Haile Selassie’s three-day visit to Jamaica in April 1966. From his arrival until his departure, he was greeted at every public appearance by throngs of Jamaicans, including a multitude of Rastas decked out in their symbolic colors of red, green, and gold. Rastas were among the invited guests at the Vale Royal residence of the prime minister and at fancy hotels where events were held in honor of Selassie. According to reports, some members of the movement were even granted a private audience with the emperor. While Selassie publicly declared that he was not a divine personage, Rastas reported that he confirmed his divinity to them in private, and requested that they work for the liberation of Jamaica before repatriating. After Selassie’s visit, the phrase liberation before repatriation gained currency among Rastas, and the fervor for repatriation seems to have diminished accordingly. Despite the new emphasis on the need for liberation, the visibility and civility of Rastas at public and private functions conferred a measure of legitimacy on the Rastafarian movement.

By the late 1960s, signs of the changing perception and fortunes of Rastafari were becoming evident. One sign was the diffusion of Rastafarian perspectives and symbolism throughout society and particularly among young people and radical intellectuals. Young people, including many from middle-class families, assumed the Rastafarian mode of dress (knitted caps and the colors red, green, and gold), mode of speech, and ideological stance vis-à-vis the oppressive nature of Jamaican society. Many black intellectuals, who had adopted the black nationalism of the Black Power movement in the United States, found a vernacular expression of such nationalism in Rastafari and established dialogue with the movement. This is best exemplified by the Black Power radical Walter Rodney, a history professor at the University of the West Indies, Mona.

Another sign was the growing influence of Rastafari on local popular music. In the 1950s, Rastafari adopted an African drumming style that had been preserved in Jamaica by a cultural group called the Burru. Rastas made this style into their ritual music and regarded it as having mystical power for use in the fight against oppression. In the early 1960s, Count Ossie, a Rastafarian drummer, arranged and accompanied “O Carolina,” which became a hugely popular song in Jamaica. For the first time, Rastafarian rhythms were incorporated into popular music. After the recording of “O Carolina,” Ossie’s compound in East Kingston became a gathering place where local musicians congregated and participated in lengthy jam sessions, thus fostering the exchange of musical ideas. These and other musicians began to incorporate Rastafarian rhythms into reggae music, and they eventually reproduced the whole range of Rastafarian rhythms on modern instruments.

The incorporation of Rastafarian rhythms into Jamaican popular music was followed by the insertion of Rastafarian spirituality and social criticism into the lyrics of popular songs. Lyricists, whether they were Rastas or not, tended to aim their barbs at the establishment, employing the verbal tools and the critical perspective of Rastafari. No one did this with more clarity and consistency than Bob Marley. His growing social consciousness and his proximity to his Rastafarian neighbors eventually led him to embrace Rastafari. In a short time, Marley made himself the public persona and international ambassador of Rastafari and reggae. Through his considerable repertoire, from “Concrete Jungle” to “Redemption Song,” Marley became the voice of the marginalized, expressing their critical assessment of the values and institutions of the West, their resolve and resilience in the struggle against extreme odds, and their determination to resist and rebel against their oppression.

Despite their activism around issues relating to poverty, the importance of African heritage, repatriation of blacks to Africa, and the legalization of ganja, Rastas have traditionally despised politics, calling it politricks, to indicate their belief that it was marked by deception and trickery. However, some members of the movement have made forays into Jamaica’s electoral politics. Most notable are the candidacies of Ras Sam Brown in 1961, Ras Astor Black of the Jamaica Alliance Movement in 2002 and after, and members of Imperial Ethiopian World Federation Party in 2003. In all instances, Rastafarian candidates received minimal support at the polls. Nevertheless, Rastafarian ideas, symbols, and lingo and Rastafari-inspired songs have been tools of political electioneering in Jamaica, as was particularly evident in the 1970s.

During the lead-up to the 1972 Jamaican general election, the PNP leader, Michael Manley, presented himself as the champion of the poor masses. In doing so, he co-opted many of the ideas and much of the language used by Rastas in their criticism of Jamaica’s sociopolitical establishment. Specifically, he painted the members of the ruling Jamaica Labor Party as agents of Babylon, and presented himself as Joshua (of Biblical fame), presumably appointed by God to “beat down Babylon” and establish justice for all. A central symbol in this political drama was a walking stick continuously brandished by Michael Manley. Manley claimed to have received the stick from Haile Selassie during a visit to Addis Abba. It was dubbed the Rod of Correction and portrayed as symbolic of Manley’s authority, bestowed by Jah (God) or Selassie, to right the wrongs of Jamaican society.
Probably the most effective electioneering tool in Jamaica in the 1970s was reggae music, with its Rastafari-inspired lyrics. Manley and the PNP adopted such songs as “Better Must Come,” “Beat Down Babylon,” and “Dem Ha Fi Get a Beatin” to convey to the masses that they intended to change fundamentally social conditions in Jamaica. Such Rastafarian terms as “One Love,” “Peace and Love,” and “Hail De Man” flowed from the lips of PNP politicians in a streetwise and populist attempt to woo the young and poor who made up the majority of the voting public. While the PNP referenced elements of Rastafari more extensively and managed to win the 1972 and 1976 elections, the JLP was also quick to invoke the vernacular culture deeply influenced by Rastafari. Its campaigners made liberal use of reggae songs, and its leaders, such as Hugh Shearer and Edward Seaga, gave speeches that were laced with Rastafari-inspired street lingo. By the 1980 election, which was won by the JLP, the overt use of Rastafarian references and language was clearly on the wane in political campaigning. Manley had become steeped in Marxist/socialist rhetoric, whereas Seaga, who had become the leader of the JLP, appealed more to the folk-Christian sensibilities of followers of Revivalism and Pentecostalism, religious movements that are even more pervasive in Jamaican society than Rastafari. Seaga had been a promoter of Jamaican folk culture since the 1960s, had done ethnographic research on Revivalism, and had been rumored to be a secret practitioner of its healing arts.

Though politicians may have been self-serving when they co-opted Rastafarian lingo and symbolism as electioneering tools, they unwittingly bestowed legitimacy on both. At the same time, reggae’s status was on the rise. Artists such as Desmond Decker, Toots and the Maytals, and Jimmy Cliff gained international success, while Bob Marley and the Wailers achieved superstardom, making them the epitome of reggae’s cultural ascendancy. Despite earlier misgivings, Jamaicans of all walks of life came to embrace reggae as Jamaica’s cultural gift to the world. Marley was eventually awarded Jamaica’s second-highest honor, the Order of Merit, and at his passing he received a state funeral. Since then, reggae and Rastafari have become a source of inspiration for artistic and cultural production in Jamaica, the Caribbean, and beyond.

From its inauspicious beginnings among the marginalized in Jamaica, Rastafari has blossomed into a global religious and cultural movement. Today Rastafari claims followers throughout the Caribbean, including Cuba; in West and Southern Africa; throughout North America and Europe; in Central and South America, especially Brazil; in New Zealand and Australia; and even in Japan. The spread of Rastafari has been facilitated by international travel and migration and by the worldwide distribution of reggae via the global music industry and communication technology.

The post–World War II era saw the immigration of numerous Jamaicans, including Rastas, to England and North America. When many of the children of these immigrants looked to Jamaica in the 1960s and 1970s for something to counter the alienation they felt in their parents’ adopted homelands, it was Rastafari that provided them with both a critique of alienating Western culture and a sense of self that celebrated their African heritage. Students from other Caribbean islands studying in Jamaica, and Jamaicans traveling to and studying in other parts of the Caribbean, were the main agents of the spread of Rastafarian ideas and practices throughout the Caribbean, especially to Barbados, Cuba, Dominica, and Trinidad and Tobago. Over the years, Rastas have traveled far and wide throughout the world, taking their message with them, and visitors to Jamaica from around the world have also contributed to the dispersal of the Rastafarian message.

Probably even more important than travel and migration has been the spreading of the Rastafarian message through reggae music. Through the global marketing of reggae and the ubiquity of modern communication technology, even people who have never seen a Rasta in the flesh have come in contact with the message of Rastafari and have found resonances with their own experiences and aspirations in the music. Thus, we find reggae and Rastafari inspiring the struggles of people around the world: the Maoris of New Zealand, the Aborigines of Australia, the Punjabis in India, Native Americans, and the Palestinians.

The earliest studies on Rastafari tended to focus on its rejection of Jamaica, its call for repatriation, and its deification of Haile Selassie. Using a label commonly applied to new religious movements in colonial or former colonial societies, these studies identified Rastafari as an example of messianic millennialism (Simpson 1955; Barrett 1977; Kitzinger 1969). The next wave of studies tended to highlight the political dimensions and revolutionary potential of Rastafari and hence saw Rastafari as a call for social change in Jamaica (Nettleford 1970; Owens 1976). The third wave was more serious about taking an ethnographic approach and about exploring the character of the Rastafari movement. These scholars described the contours of the movement, highlighting its cultural, social, and spiritual beliefs and practices (Chevannes 1994; Yawney 1978). Into the twenty-first century, the output is almost too varied for categorization. The spread of Rastafari and its growing globalization have led to mutations and transformations. Most academic studies have built upon the second and third waves mentioned above. In addition, many Rastas have written accounts and interpretations of their experiences; numerous studies of reggae and its relationship to Rastafari have been published; biographies of Rastafarian reggae artists, chiefly Marley, abound; and various studies of Rastafari in a range
of locations (Britain, West Africa, South Africa, Brazil, Trinidad, Dominica, Cuba) are now available.

RATE OF EXPLOITATION

According to Karl Marx, exploitation takes place under capitalism through the extraction of surplus value. In the capitalist mode of production, the surplus takes the form of profits appropriated by the capitalist, and exploitation results from the working class producing a net product that can be sold for more than they receive as wages. Marx made a distinction between labor and labor power that is important for understanding the source of profits. Labor power is the sum total of abilities (spiritual and physical) a worker uses to produce use-values. It is a commodity owned by a laborer but sold in the labor market, and its value—as with any other commodity purchased by the entrepreneur—equals the socially necessary labor time required for the production of goods and services consumed by a laborer for the reproduction of himself and his family. Labor, on the other hand, is the use of labor power—that is, the amount of useful labor provided by a worker in a given period of time (an hour or a day). According to Marx, the amount of labor spent in producing a commodity determines that commodity’s value.

In the capitalist mode of production, the labor time required for the production of the means of subsistence for the laborer is smaller than the labor time actually provided by him to his employer during a labor day. Hence, for any given time period, the laborer produces more value than the equivalent of his or her remuneration (wage). This difference Marx calls unpaid labor or surplus labor. The net product produced by the worker during the labor time that is above and beyond the time needed for the reproduction of the labor class is called surplus value and is the foundation on which the Marxian theory of profit rests. Hence, the amount of surplus value (s) a worker produces is the difference between the value he or she produces and the value of his or her labor power (v).

The value produced by a worker during a labor day is determined by the conditions of the labor process, whereas the value of his or her labor power is determined by the conditions of the labor market and the value of the goods a worker must consume. The ratio s/v represents the rate of surplus value (sometimes called the rate of exploitation), because it indicates how much value has been produced during a labor day beyond the value that laborers actually receive as remuneration. This surplus product is appropriated by the employers, who are the owners of the means of production.

In a capitalist mode of production, the driving force of the system is the self-expansion of capital that can be attained with the creation of more surplus value. This is because profits are realized as surplus value (through the selling of commodities in the market), and the more surplus value there is, the higher are the profits and profit rates, and by extension, the easier is the process of accumulation and concentration of capital. If π stands for profits and approximates the surplus value and w stands for wages and approximates the variable capital (that is, the wage proportional to labor hours spent for the reproduction of the laborer and his family), then the rate of surplus value or exploitation can be approximated in a real...
economy by the ratio \( \pi/w \), which gives us a good idea of the income distribution in the economy. The higher the profit-wage ratio, the higher the distribution of income in favor of profits and, eventually, the higher the investment.

Several economists (right-wing and left-wing) have argued that the constant decline in the above ratio in most economies since the end of World War II indicates an increase in the wage bill relative to profit share, the redistribution of income toward labor, and the lessening of the exploitation rate. One of the reasons claimed for this rise in the wage bill is the unionization of the labor force and the concomitant “malfunctioning” of the labor market (that is, wages do not fall to the level necessary to clear the markets). The same economists argue that the slowdown in growth rates observed after the 1970s is also due to the rise in the wage bill, because that rise deprives capital of the profits needed for investment. Hence, policymakers, based on this evidence, promote the liberalization of the labor market in an attempt to increase profit share.

The counterargument to these suggestions comes from Marxist economists who claim that before the profit-wage ratio can be accurately measured, a distinction must be made between productive and nonproductive labor, to ensure that the correct surplus value \((s/v)\) is computed. Relevant studies have shown that the rate of surplus value has increased, indicating an increase in labor exploitation. This increase in the rate of surplus value is absolutely consistent with the falling rate of profit \((r)\) during the same time period. In fact, by definition the rate of profit is \(r = s/(c + v)\)—that is, surplus value over capital invested (circulating and variable)—or \(r = (s/v) / [1 + (c/v)]\). The term \(c/v\) represents the organic composition of capital, an index of capital intensity whose rate of increase is higher than that of the rate of surplus value, giving rise to a falling rate of profit.

RATE OF PROFIT

The rate of profit is defined as ratio of profits, the difference between total revenues and total costs, to the capital advanced for production. Theories differ in terms of how both profits and capital are defined. The profit rate is also defined on the aggregate or economy-wide level, the industry level, and the firm level. In most theories with competitive markets, capital will flow to higher-profit firms, and there will be a tendency for the rate of profit to be equalized among firms in the long run.

The rate of profit is a category not generally modeled in standard neoclassical economics. Indeed, in general equilibrium models with competitive markets, the rate of profit will tend toward zero. Instead, neoclassical economists focus on the existence of rent—that is, returns to factors of production such as mineral resources or special talents that are not generally reproducible—rather than profits. In contrast, the rate of profit is the central category in Marxian economics. The rate of profit is also an important category in Keynesian, neo-Keynesian, and post-Keynesian economics. As a result, most of the theoretical work on this subject comes out of these fields, particularly Marxian economics.

This article examines trends since the end of World War II in the rate of profit in the United States and reviews some of the theoretical literature on the rate of profit in the Marxian tradition.

TRENDS IN THE RATE OF PROFIT IN THE UNITED STATES SINCE WORLD WAR II

It is helpful to begin by considering the relation between productivity and earnings. In the case of an economy characterized by competitive input markets and constant returns to scale, it follows from a standard neoclassical aggregate production function that wages and labor productivity should grow at exactly the same rate. (In this case, \(w = \sigma X \varepsilon L = \varepsilon L X\), where \(w\) is the wage rate, \(X\) is total output, \(L\) is total employment, and \(\varepsilon\) is output elasticity of labor, which equals the wage share in this special case.) The wage is thus a fixed percentage of overall labor productivity, and the wage share is also constant (the wage share \(wLX = \varepsilon L\)).

Basic data are from the U.S. Bureau of Economic Analysis National Income and Product Accounts, as well as its series on net capital stock (data are all available on the Web site supported by the U.S. Bureau of Economic Analysis). From 1947 to 1973 real wages in the United States grew almost in tandem with overall labor productivity growth (see Figure 1). While the latter averaged 2.4 percent per year, the former ran at 2.6 percent per year. Labor productivity growth plummeted after 1973. Between 1947 and 1973, it averaged 2.4 percent per year.
whereas from 1973 to 2003 it averaged only 1.0 percent per year. The period from 1973 to 1979, in particular, witnessed the slowest growth in labor productivity during the postwar period, 0.5 percent per year, and the growth in real employee compensation per full time equivalent employee (FTEE) actually turned negative during this period. Since 1979, the U.S. economy experienced a modest reversal in labor productivity growth, which averaged 1.2 percent per year from 1979 to 2003, whereas real wage growth was 0.6 percent per year. In particular, the historical connection between labor productivity growth and real wage growth appears to have broken down after 1973.

If productivity rose faster than earnings after 1973, where did the excess go? The answer is increased profitability in the United States. The Bureau of Economic Analysis defines profits as total gross property-type income, including corporate profits, interest, rent, and half of proprietors’ income. The definition excludes the capital consumption allowance (CCA). The net rate of profit is defined as the ratio of total net property income to total private net fixed capital. The net profit rate declined by 7.5 percentage points between 1947 and its nadir, 13.1 percent, in 1982 (see Figure 2). It then climbed by 6.0 percentage points from 1982 to 1997 but fell off by 1.1 percentage points between 1997 and 2001. However, after 2001, it surged upward, reaching 20.5 percent in 2003, fairly close to its postwar high of 22.7 percent in 1948.

Figure 2 also shows trends in the net profit share in national income. It rose by 2.4 percentage points between 1947 and its peak value of 32.0 percent in 1950 and then fell by 7.2 percentage points between 1950 and its low point of 24.8 percent in 1970. It then generally drifted upward, rising by 4.2 percentage points between 1970 and its next high point of 29.1 percent in 1997. It then fell off by 1.7 percentage points between 1997 and 2000 but once again climbed upward to reach 29.4 percent by 2003. The results show a remarkable recovery in both the overall rate of profit and the profit share since the early 1980s in the United States.

A number of studies have documented these trends. Earlier ones such as the 1986 study by Edward Wolff and the 1994 study by Anwar Shaikh and Ahmet Tonak looked into the factors responsible for what seemed to be a secular decline in the profit rate in the United States from the late 1940s to the early 1980s. The rise in profitability since the early 1980s has been discussed by Gérard Duménil and Dominique Lévy (2002) and Wolff (2001). Duménil and Lévy (2002) also provide time trends on the profit rate for Germany, the United Kingdom, and particularly, France. All three countries, as with the United States, showed declines in profitability from 1960 to the early 1980s and a sharp reversal through the late 1990s. Both Lewis Corey in 1934 and Duménil and Lévy in 1993 presented data on movements in the
rate of profit in the United States from the early part of the twentieth century. These authors make the case that the onset of the Great Depression beginning in 1929 coincided with a sharp decline in the rate of profit in the United States.

THEORIES OF THE RATE OF PROFIT
As noted above, movements in the rate of profit have long occupied Marxian economists. Marx himself argued that the rate of profit would tend to decline over the long run. His “law of the tendency of the rate of profit to fall” states that over time, the organic composition of capital (the ratio of capital valued in nominal terms to the wage bill) would rise, thereby causing the general rate of profit to fall (Marx 1894). This law has been subject to criticism on theoretical grounds as discussed, for example, by Paul Samuelson in his 1971 article, though more recent literature has reversed some of these theoretical criticisms, as developed by Duncan Foley in his 1986 work.

Despite the theoretical disagreements, Marx’s theory does provide a useful framework in which to analyze factors that affect movements in the rate of profit, and many papers have done this. Marx’s law can be formalized as follows (where variables in current prices are specified instead of labor values): The ratio of total profits to total worker compensation (the rate of surplus value) is defined as: \( e = \frac{\pi}{wL} \), where \( \pi \) is total profits, \( w \) is the wage rate, and \( L \) is total employment. The economy-wide organic composition of capital \( s \) is given by: \( s = \frac{p_kK}{wL} \), where \( p_k \) is the price of capital and \( K \) is total capital. The standard capital–labor ratio (the technical composition of capital) is given by: \( t = \frac{K}{L} \). The relation between the organic and technical composition of capital can be derived as: \( s = t \left( \frac{p_k}{w} \right) \). The rate of profit \( r \) is defined as: \( r = \frac{\pi}{p_K} \).

Here it should be noted that the rate of profit is defined as the ratio of profits to the current dollar value of capital. Finally, it can be shown that the rate of profit \( r = \frac{e}{s} \), the ratio of the rate of surplus value to the organic composition of capital.

Marx believed that the rate of surplus value, or the rate of exploitation as he also termed it, was relatively fixed over time because it reflected the social relations of production, which were relatively stable over time. He also argued that the organic composition would rise over time because of the increasing capital intensity of production and that this would lead to a falling rate of profit in the long term. The problem in this line of reasoning is that while it was true that the capital–labor ratio did tend to rise over time because of the rising capital intensity of production, the price of capital relative to labor also tended to fall over time, offsetting the increase in the capital–labor ratio. Empirically, the organic composition also tends to remain relatively stable over time. Marx did discuss many mitigating factors to his “law” and, indeed, referred to it as a “tendency” rather than in absolute terms.
Two other very important contributions to the theoretical literature come out of the Keynesian tradition. The first, by Michał Kalecki (1971), develops a model in which national income is directly determined by autonomous investment and profits, in turn, are determined as a fixed share of national income. This model led to an extensive literature tracking the profit share in national income. The second, by Piero Sraffa (1972), develops the concept of the maximum rate of profit. He shows analytically that the maximum rate of profit depends exclusively on the technology of production and is independent of the wage (and therefore profit) share.

RATIONAL CHOICE THEORY

Rational choice theory (RCT) in sociology draws on the tradition of utilitarian philosophy, and insights from the field of economics. While the central elements of RCT found expression in some earlier sociological accounts (most notably exchange theory), the formal development of RCT in sociology came only recently. Sociologists tend to explain human behavior as patterned outcomes of macro-level causes (culture and social structure) that have an impact on individual and groups. In contrast, RCT focuses on the intentional, goal-oriented behavior of individual actors. Social interaction, and the development of cultural systems and social structure, reflect the outcome of the purposive pursuit of individual self-interest.

The methodological individualism of RCT clearly sets it apart from traditional sociological accounts. Rational choice theorists maintain that the starting point for explanations of macro-level structures and group behavior is determined by the behavior of the core element of such systems, the individual actor. Individuals, including the corporate actor, are characterized as rational actors who choose actions designed to maximize their own individual interests—the satisfaction of their needs and wants:

1. Actors calculate the benefits (utility) of expected outcomes resulting from particular activities and interactions.

2. Actors take into account the expected costs of particular behaviors and include in these calculations the variable utility related to alternative courses of action (opportunity costs).

3. Actors engage in actions they expect to maximize their own interests.

Recognizing that other factors (cultural norms and values as well as the structure of the existing social con-
text) also influence decision-making, RCT stipulates that individuals nonetheless employ a utilitarian strategy designed to insure their access to and control over desired resources (material and nonmaterial). RCT offers an explanation of how macro-level structures emerge from the micro-level, purposive activity of individuals.

Social exchange theory (Homans 1961) represents an early approach that incorporated this image of the rational actor. Whereas George Homans's approach rests on a behaviorist conception of the individual actor motivated by rewards and punishments, contemporary RCT (Coleman 1990) simply argues that individuals act as if they are rational, and that human rationality needs no further explanation. RCT is not concerned with how actors define utility, or what particular objectives they seek to acquire; rather, the focus is simply on the fact that actions are chosen to achieve such ends efficiently.

RCT characterizes social interaction as social exchange. Individuals enter into interaction with others when the potential rewards (tangible and intangible) outweigh the calculated costs. Although it is not always possible for individuals to satisfy all their needs, they will choose alternatives they think lead to the greatest maximization of their individual interests within the constraints of particular situations. Sustained interaction, and the emergence of social structure, depends on the recognition, from the perspective of each individual involved, of the ongoing effort to achieve fulfillment of individual self-interest (Homans 1961).

Within a social context, a variety of factors affect the calculation of individual utility. The scarcity of available resources and differential access to those resources can limit opportunities for specific actors. Individuals who possess scarce resources can use them to further their own interests. Differential control of available resources produces differentials in power, allows for control over the exchange process, and opens up the potential for exploitation. Individual actors also vary in their relative dependence on the utility associated with expected outcomes, and the costs involved in pursuing particular actions versus others (opportunity costs) require consideration as well. The rational actor does not choose one goal over another because of its overall value, but due to the distribution of resources related to achieving that goal, the feasibility of success in obtaining the goal, the relative costs of any exchange involved in pursuit of the goal, and the variable value (objective and subjective) assigned to alternative strategies and their related rewards (Ritzer and Goodman 2004).

The development of sustained interaction and the emergence of a social system present certain problems for RCT:

1. If all actions are based on self-interest, why do individuals cooperate? (The so-called free-rider problem.)

2. What are the roles of institutionalized norms and sanctions, as well as values, that may both limit particular courses of action and encourage others (and how do these elements develop)?

Two types of collective interaction are involved—structured and unstructured. For organized, structured groups and organizations, participation by the rational actor is based on the costs involved in participation versus relative benefits accrued. The structuring of the context is important, with “selective incentives” altering the rewards/cost equation (Olson 1965; Hechter 1987). An actor may calculate that the relative costs of an exchange are outweighed by the potential benefits of sustained cooperation; however, such calculations are oftentimes based on unequal distribution of desired resources. Control of desired resources provides an individual or corporate actor the power to force (or legitimate) the surrendering of individual control and decision-making from one actor to others. Whether voluntary or not, the surrendering of authority and rights possessed by one individual to another produces a relatively stable, independent social structure and a redirection of purposive behavior based on both reciprocity and restraint (Scott 2000). Unstructured (collective) behavior emerges when individual maximization of utility becomes defined in terms of unilateral (nonreciprocal) transfer of control to the collective. As the individual cedes authority to a collective based on the recognition that individual success is only served through collective action, a dynamic character to social action ensues, resulting in the potential for disorder or change (Coleman 1990; Ritzer and Goodman 2004).

As collective interaction persists, a normative system is established, supporting the interests of actors with control over scarce resources, and the mutual interests of actors who recognize the utility of cooperative engagement. James Coleman (1990) maintains that norms are created and enforced by people who see benefits resulting from obedience, and harm or costs associated with violation. Norms allow the individual to transfer partial control within a shared system of rules, and relative maximization of utility is achieved by gaining partial control over the behavior of others. Normative structures legitimate the authority of particular collective actors based on their control over desired resources, or represent actors’ trust or anticipated long-term reciprocity (Blau 1964; Scott 2000).

Although criticized for its reductionist approach, for ignoring the role of cultural values and subjective meaning in individual and group behavior, and for an overreliance on the idea of the rationality of the human actor,
RCT retains support among sociologists. Advocates claim that RCT provides an integrated theoretical analysis that bridges the differences across disciplines in the social sciences.

RATIONAL EMOTIVE THERAPY
SEE Psychotherapy.

RATIONALISM
Rationalism comes in various versions and makes wider or narrower claims. The idea underlying most versions is that reason is the most characteristic faculty of Homo sapiens. Appeal to reason is part of traditional wisdom, yet traditional (ancient Greek) rationalism includes an out of hand dismissal of traditional wisdom. The modern version of this dismissal is the radical demand for starting afresh (Enlightenment rationalism) and admitting only ideas that are proven, absolutely certain, and fully justified by rigorous proof. Science begins with rejecting all doubtful ideas. Francis Bacon initiated the idea that traditional unfounded views are the causes of all error; René Descartes tried to ignore all doubtful ideas and start afresh from nothing. David Hume began his investigations in efforts to delineate all that is certain while ignoring all else; he and many others, from Denis Diderot to Pierre-Simon de Laplace, took it for granted that Isaac Newton's success was due to his adherence to Bacon's advice. Auguste Comte and T. H. Huxley took it for granted that other fields will be as successful if they only jettison tradition more fully; Ludwig Wittgenstein went further and said only scientific assertions are grammatical (positivism, scientism).

ENLIGHTENMENT RADICALISM AND THE ROMANTIC REACTION
Yet what proof is no one knew. Mathematics was the paradigm of proof, and the success of physics was largely ascribed to its use of mathematical methods, a practice for all to emulate. What is that method, and how can it be applied to the social domain? How does the relinquishing of tradition help word theories mathematically? This was unclear even after the discipline of statistics was developed enough to become applicable to some social studies (as in the work of Adolphe Quételet, 1796–1874). Yet clearly as usefulness gives rational thought its initial (even if not final) worth, at least the rationality of action is obvious: its goal-directedness. Hence the study of rationality is vital for the study of the rational action that is the heart of the study of humanity. Whereas students of nature seldom pay attention to the rationality and the scientific character of their studies, students of humanities are engrossed in them. And whatever their views on this rationality, at least they openly center on it. Thus in the opening of his classic An Inquiry into the Nature and Causes of the Wealth of Nations (1776), Adam Smith declares his intent to ignore irrationality, no matter how widespread it is. Slavery is widespread, yet everyone knows that putting a worker in chains is no incentive, he observed.

The Enlightenment movement deemed Smith's argument obvious; this led to its dismissal of human history as the sad story of needless pain caused by ignorance and superstition. This was an error. The advocacy of the abolition of slavery came in total disregard for its immediate impact on the lot of slave owners. Smith spoke of rationality in the abstract. Because high productivity depends
on the division of labor and because this division leads to trade, freedom is efficient. Selfish conduct is rational as long as it is scientific, that is, undogmatic. Life in the light of reason is egalitarian, simple, and happy. This abstract reasoning led to concrete results, including the French Revolution and its terror and wars. Edmund Burke and Georg Wilhelm Friedrich Hegel blamed the radicalism of the revolution for its deterioration into terror. The reaction to the French Revolution was aggressively hostile to radicalism, to egalitarianism, and even to reason (Hegel).

MARX AND AFTER
Karl Marx wedded the two great modern movements, the radical Enlightenment movement and the Romantic reaction to it. The former had the right vision, and the latter had the historically right view of the obstacle to its realization. Smith-style harmony between individual and society has no place in traditional society. Hence the institution of enlightened equality is an essential precondition for it. The realization of the radical dream of harmony requires civil war. But it is certainly realizable, he insisted.

Marx's critique of radicalism from within is as popular as ever. We are chained to our social conditions, and rationalism cannot break them. Max Weber, the author of the most popular alternative to Marx's ideas, stressed this; so do all the popular radical critics of the ills of modern (“bourgeois”) society, chiefly imperialism, racism, and sexism, perhaps also alienation from work. These critics puzzle the uninstructed, as they seem to belabor condemnations of obviously indefensible aspects of modern society. But they do something else; they advance a thesis. Induction will not go away by sheer mental exercises. Are there any reasonable people who disagree with this thesis? It is hard to say. Perhaps some thinkers still follow the central thesis of the Enlightenment movement. If such people do exist (as seems true but not obviously so), then they are the neoliberals, the Chicago school of economics, which is not confined to economics, as it preaches the idea that a world with free markets still is the best of all possible worlds, even though it is far from ideal (Friedrich A. von Hayek).

VARIANTS OF RATIONALISM
What then is rationalism? Of the alternative views on reason, which can count as variants of rationalism? Consider pragmatism, the view of the useful as the true (Hegel, William James, John Dewey). It is unsatisfactory, because assessments of usefulness may be true or not; but is it a version of rationalism? Consider the traditionalist reliance on the test of time (ordinary-language philosophy; neo-Thomism). The assessment of the relative worth of traditions may be cultural (Martin Buber, Amitai Ezioni; communitarianism) or intellectual (Michael Polanyi, Thomas S. Kuhn; postcriticalism). It is unsatisfactory, as these assessments may be true or not; but is it a version of rationalism? There is no telling. The same holds for appeals to other criteria for truth. These are common sense (Hume, Smith, Thomas Reid, Adam Ferguson, George Edward Moore), the intuitions of Great Men (Johann Gottlieb Fichte, Hegel, Martin Heidegger), higher religious sentiments (Friedrich Schleiermacher, Fyodor Dostoevsky, Leo Tolstoy), and superior tastes (Richard Rorty). Are these variants of rationalism? Do they lead to more reasonable human conduct? The standard claim is that their asset is in their ability to maintain social stability. But in the early twenty-first century stability is unattainable and even deemed inferior to democratic controls (Karl R. Popper).

There is no consensus about whether the counsel to limit reason and admit religion is rationalism proper (Moses Maimonides, Saint Thomas Aquinas, Robert Boyle, Moses Mendelssohn, Polanyi) or not (Immanuel Kant, David Strauss, Ludwig Feuerbach, Sigmund Freud, Bertrand Russell, Adolf Grünbaum). The only consensus is about the defiance of reason (Søren Kierkegaard, Max Stirner, Joseph Arthur Comte de Gobineau, Georges Sorel, Friedrich Nietzsche, D. H. Lawrence, Heidegger, perhaps also Paul Feyerabend). The only generally admitted necessary condition for rationalism is the demand to side with reason. Therefore it is fashionable to limit rationalism by allowing the taking of a single axiom on faith while otherwise swearing allegiance to reason (Polanyi, Richard H. Popkin, Pope John Paul II; fideism). The default view should then be that this allegiance suffices. Add to this the consensus around a necessary condition for this allegiance. It is the critical attitude, openness to criticism, the readiness to admit the success of the criticism of any given view. Consider the view that the critical attitude is sufficient as the default option (Popper) and seek valid criticism of it that may lead to its modification, to the admission of some unavoidable limitations on reason, whether in the spirit of Marx or in that of his critics. The need for this limitation comes from purely philosophical considerations. Hume said that we need induction for knowledge and for practice, yet it is not rational (it has no basis in logic); instead, we rely on it out of habit and necessity and this is the best we can do. A popular variant of this is that because induction is necessary, it is in no need of justification (Kant, Russell). Another variant takes it on faith (Polanyi, Popkin; fideism). Is induction really necessary?

This question is welcome. Since finding alternative answers to a worthy question improves their assessment, they are all worthy. Hence all versions of limited rationalism are welcome—as hypotheses to investigate (Salomon Maimon, Popper). This is the power of the method of always trying out the minimal solution as the default.
CRITICAL RATIONALISM

Critical rationalism is revolutionary because it replaces proof with test; it replaces radical, wholesale dismissal of ideas with the readiness to test piecemeal (Albert Einstein, Popper; reformism). The demand to prove thus yields to the critical attitude (William Warren Bartley III, Willard Van Orman Quine; non-justificationism), recognizing that theories possess graded merit (Einstein, Leonard Nelson, Popper; critical rationalism)—by whatever rule we happen to follow, no matter how tentative. Rules are then hopefully improvable (Charles Sanders Peirce, Russell, Popper; fallibilism). Hence diverse rules may serve as competing criteria or as complementary. Being minimalist, critical rationalism invites considering some older theologians as allies, although not their contemporary followers. Unlike radical rationalism, critical rationalism is historically oriented. (It is the view of rationality as relative to contexts and of truth as absolute, as a guiding principè à la Kant.)

This invites critical rationalism to enlist rational thought as a category of rational action (Ian C. Jarvie and Joseph Agassi). And this in turn invites the study of rationalism as an aspect of extant scientific research. It also invites comparison of the various versions of rationalism as to the degree of their adequacy to this task: take scientific research as it is, warts and all, and examine its merits and defects according to the diverse alternatives. This attitude is new and expressed in various studies of the sociology of science, so-called, that often spread over diverse disciplines, including political science and even criminology no less. This renders a part of the project of rationalism the assessments of the intellectual value of the outcome of research, theoretical, practical, or cultural—or even aesthetic. The only intellectual justification of a scientific theory, said Einstein, is its ability to explain; its best reward is its successor's admission of it as approximate. In this way he stressed that the aim of research is to explain in the hope of approximating the truth. This is open to debate. Social science as a whole may serve as a test case, with the sociology of science at the center of the debate on this matter.

Historically, rationalism doggedly accompanied studies of nature, not social studies. What in these should rationalism approve of? Discussion of this question allowed rationalism to inform the social sciences. A conspicuous example is the vagueness in social studies of the boundaries between philosophy, science, and practice that still invites open discussion. Anything less is below the minimal criterion of the critical attitude.

Critics of minimal rationalism find criticism insufficient, since positive criteria of choice need justification. If so, then rationalism is back to square one. If not, then positive criteria must be tentative, and the issue must shift from their justification to efforts at their improvement. Some do not like this, as it rests on their initial choice that was too arbitrary. They prefer to return to the initial criterion and replace it with the least arbitrary one. They are radicals. The clash is thus between the radical and the critical version of rationalism—as well as between them and fideism.

The agenda of rationalism—in philosophy, in science, or in practice—is the same: heightening the critical attitude, seeking improvement through criticism everywhere. Where is the starting point? How are we to decide on our agenda? Parliamentary steering committees decide on agendas. The commonwealth of learning, however, is its own steering committee. Those concerned to promote rationalism should do their best to put discussions of it high on the public agenda.

BIBLIOGRAPHY

RATIONALITY

Rationality in its ordinary sense is reasonableness. It requires justified beliefs and sensible goals as well as judicious decisions. Scholars study rationality in many ways and adopt diverse views about it.

Some theorists adopt a technical definition of rationality, according to which it is just maximization of utility. This definition is too narrow. It considers only adoption of means to reach ends, that is, instrumental rationality. It also evades a major normative question, namely, whether rationality requires maximization of utility. The definition simply stipulates an affirmative answer.

A traditional theory of the mind takes reason as a mental faculty. It characterizes humans as rational animals because they have the faculty of reason, whereas other animals lack that faculty. According to this tradition, any behavior resulting from reasoning is rational. This account of rationality sets the bar low. Most accounts hold that the products of reasoning must meet certain standards before they qualify as rational. A conclusion, for example, must fit the evidence to be rational. It is not rational simply because it results from an inference. Reasoning must be good to yield rational beliefs reliably.

For simplicity, some theorists take being rational to be the same as being self-interested. Being rational differs from being self-interested, however. Promoting self-interest means doing what is good for oneself. Doing what is good for others promotes their interests, not one's own. Rationality may require some measure of self-interestedness but does not require exclusive attention to self-interest. It permits altruism, as Amartya Sen (1977) and Howard Rachlin (2002) explain.

Epistemologists treat justified belief. Under one interpretation, a justified belief is just a rational belief. However, other interpretations of justification are common because a conventional view takes knowledge to be true, justified belief. Making justification fit into that view of knowledge motivates taking justified belief to differ from rational belief. Children rationally believe many true propositions without having knowledge of them because the grounds for their beliefs do not amount to justification.

Rationality is a normative concept. Principles of rationality state how people should behave rather than how they behave. However, some fields assume that people are rational by and large and then use principles of rationality to describe and explain behavior. For instance, some economic theories assert that consumers make purchases that express their preferences. They take this as a fact about consumers' behavior rather than as a norm for it. Psychologists seeking to infer a person's beliefs and desires from the person's behavior may assume that behavior maximizes utility. The assumption simplifies inference of beliefs and desires. Several prominent representation theorems show that if a person's preferences concerning acts meet certain axioms, such as transitivity, then one may infer the person's probability and utility assignments (given a choice of scale) from the person's preferences, under the assumption that preferences concerning acts agree with their expected utilities. Richard Jeffrey ([1965] 1983) presents a theorem of this sort.
PHILOSOPHY AND RATIONALITY

Philosophy treats rationality because it is the most important normative concept besides morality. Understanding how a person should conduct her or his life requires a thorough understanding of rationality. Being a rational person requires being sufficiently rational in the various aspects of one's life. Common principles of rationality attend to beliefs and desires and to the decisions they yield. Some principles evaluate character traits and emotions. They judge, for example, that some fears are rational and that others are irrational. Principles of rationality extend from individuals to groups. Committees may pass rational or irrational resolutions. Political philosophy evaluates social contracts for rationality. Mancur Olson (1965) investigates rational collective action and the conditions that foster it.

A traditional metaphysical question asks for the grounds of principles of rationality. What makes consistency a requirement of rationality? Are the principle's grounds conventions or something more universal? A common answer claims that natural properties realize normative properties. Consistency increases prospects for true beliefs.

A traditional practical question asks for reasons to be rational. A common answer is that being rational yields the best prospects (with respect to one's evidence) for meeting one's goals and so achieving a type of success. Decisions that maximize expected utility are more likely to be successful than decisions that do not maximize expected utility.

Some philosophers hope to derive principles of morality from principles of rationality. Kantians, for example, hold that a rational person acts in accord with moral principles. Hobbesians hold that the legitimacy of a government derives from the rationality of the social contract that creates it. Rawlsians hold that principles of justice emerge from a hypothetical social contract rational to adopt given ignorance of one's position in society.

BELIEF AND INFERENCE

A general principle states that rationality is attainable. Its attainability follows from the familiar principle that “ought” implies “can.” Well-established principles of rationality also treat formation of belief and inference. Consistency is a noncontroversial requirement. Holding inconsistent beliefs is irrational unless some extenuating factor, such as the difficulty of spotting the inconsistency, provides an excuse. Perceptual beliefs are rational when the processes producing them are reliable. Vision in good light yields reliable judgments about the colors of objects. Logic describes in meticulous detail patterns of inference that are rational. For example, if one believes a conditional and believes its antecedent, then believing its consequent is a rational conclusion. Repeated application of rules of inference to prove theorems in logic requires sophistication that ordinary rationality does not demand. Rationality requires an ideal agent to believe each and every logical consequence of her or his beliefs. Its requirements for real people are less demanding. (For a sample of principles of rationality concerning belief, see Foley 1993; Halpern 2003; and Levi 2004.)

Rationality governs both deductive and inductive inference. Principles of statistical reasoning express principles of rational inductive inference. If one knows that an urn has exactly eighty red balls and twenty black balls, then it is rational to conclude that 80 percent is the probability that a random draw will yield a red ball. Given a statistical sample drawn from a population, principles of statistical inference attending to the size of the sample and other factors state reasonable conclusions about the whole population.

PREFERENCES

Preferences may arise from partial or complete consideration of relevant reasons. Common principles of rational preference apply to preferences held all things considered.

The principle of transitivity requires preferring A to C given that one prefers A to B and also prefers B to C. The principle of coherence requires having preferences among acts that may be represented as maximizing expected utility. The definition of preference affects the force of such principles. The ordinary sense of preference acknowledges the possibility of weakness of will and acting contrary to preferences. However, some theorists for technical reasons define preferences so that a person acts according to preferences, so telling a person to pick an option from the top of her or his preference ranking of options has no normative force—she or he does that by stipulation.

The principle of consumer sovereignty puts basic preferences beyond criticism. Some basic preferences are irrational, however. Forming preferences among ice cream flavors one has not tasted may be irrational. Having a pure time preference may be irrational. That is, it may be irrational to prefer the smaller of two goods just because it will arrive sooner than the larger good. Certainty of having the larger good if one waits for it is a strong reason for waiting.

The chief principle of rational decision making is to pick an option from the top of one's preference ranking of options. If some options are gambles, a supplementary principle says to prefer one option to another option just in case its expected utility is higher than the expected utility of the other option. J. Howard Sobel (1994) and Paul Weirich (2001) analyze such principles of rational choice.
DECISION MAKING

Rationality evaluates free acts that an agent fully controls. Decisions are in this category; so are acts such as taking a walk. Rationality evaluates acts an agent controls directly by comparing them with rivals and evaluates acts an agent controls indirectly by evaluating their components. An agent directly controls a decision, and so rationality evaluates it by comparing it with its rivals. An agent indirectly controls taking a walk, and so rationality evaluates it by evaluating its directly controlled components. The rationality of a series of acts, such as having dinner and going to a movie, depends on the rationality of its temporal components.

Game theory, expounded in classic texts by John von Neumann and Oskar Morgenstern (1944) and R. Duncan Luce and Howard Raiffa (1957), addresses decisions people make in contexts where the outcome of one person’s decision depends on the decisions that other people make. Strategic reasoning looks for combinations of decisions that form an equilibrium in the sense that each decision is rational given the other decisions. A common principle for such strategic situations recommends making a decision that is part of an equilibrium combination of decisions. Edward McClennen (1990), Robert Stalnaker (1998, 1999), Weirich (1998), Andrew Colman (2003), and Michael Bacharach (2006) conduct critical appraisals of principles of rationality widespread in game theory.

A principle of rationality may be controversial. A common pattern for controversy begins with a claim that in some cases thoughtful people fail to comply with the principle. Some respond that in those cases people are rational and the principle is faulty. Others respond that the principle is fine and people are irrational. Still others hold that people in the problem cases actually comply with the principle, contrary to the initial claim.

For example, Amos Tversky and Daniel Kahneman (Tversky and Kahneman 1982) present cases in which people form judgments that fail to comply with the probability axioms. In their study a story describes a young woman as a political activist and a college graduate with a philosophy major. People asked to speculate about the woman’s current activities may put the probability of her being a feminist and a bank teller higher than the probability of her being a bank teller only. This ignores the law that the probability of a conjunction cannot be higher than the probability of a conjunct. Some theorists may conclude that people are irrational in their probability judgments, others that people have in mind the probability that the woman is a feminist given that she is a bank teller rather than the probability of the conjunction that she is a feminist and is a bank teller. In this particular example, few dispute the law of probability concerning conjunctions.

Kahneman and Tversky (Kahneman and Tversky 1979) also present cases in which it seems that people fail to comply with the principle to maximize expected utility. A person may prefer a gamble that pays a guaranteed $3,000 to a gamble that pays $4,000 with probability 80 percent and $0 with probability 20 percent. The same person may prefer a gamble that pays $4,000 with probability 20 percent and $0 with probability 80 percent to a gamble that pays $3,000 with probability 25 percent and $0 with probability 75 percent. Let $U$ stand for utility. If the first preference agrees with expected utilities, it seems that $U(3,000) > 0.80U(4,000)$. If the second preference agrees with expected utilities, it seems that $0.20U(4,000) > 0.25U(3,000)$ and hence, multiplying both sides by 4, that $0.80U(4,000) > U(3,000)$. Because the inequalities for the two preferences are inconsistent, it seems impossible that both preferences agree with expected utilities.

One response is to reject the principle of expected utility maximization. Another response denies the rationality of having the pair of preferences. A third response claims that people care about factors besides monetary outcomes. They may, for instance, value certainty and the elimination of risk. Then the pair of preferences may agree with broadly based expected utilities without implying inconsistent inequalities.

RATIONAL CHOICE THEORY

Rational choice theory uses principles of rationality to explain behavior. The social and behavioral sciences and even literary interpretation employ it. Proponents claim that rational choice theory yields insightful analyses using simple principles of rational behavior. Critics claim that those simple principles are too austere to adequately characterize human behavior. This debate turns on the principles of rationality at issue. Some rational choice theorists may use only principles of instrumental rationality. In that case, evaluation of basic goals is missing. Other rational choice theorists use more comprehensive principles of rationality to extend the theory’s scope. They provide for principles that evaluate basic goals.

Various applications of rationality yield distinct types of rationality, such as bounded, procedural, and substantive rationality. Herbert Simon (1982) is famous for treating these types of rationality. Principles of bounded rationality set standards for people and other nonideal agents with limited cognitive power. Contrasting principles set high standards for ideal agents with unlimited cognitive power. Rationality may require ideal agents to maximize utility, whereas it requires real people to satisfy, that is, to adopt the first satisfactory option discovered. The principle to satisfy is a principle of procedural rationality because it recommends a procedure for making a decision and does not characterize the content of the
decision it recommends. A substantive principle may recommend making a decision that maximizes utility. Whether a decision maximizes utility depends on its content. It depends on the prospects of acting according to the decision. Compliance with a substantive principle of rationality, such as utility maximization, may require a procedure that is more trouble than its outcome justifies. Spending hours to make a move in a chess game may sap the game’s fun. Sometimes thorough calculation is too costly, and one should make a quick decision. It may be sensible to adopt the first satisfactory course of action that comes to light instead of running through all options, calculating and comparing their utilities.

An evaluator may apply a substantive principle to an act already performed. The principle judges the act without regard for the process that produced it. The principle of utility maximization gives an optimal option high marks whether it arose from a thorough or a hasty review of options. The principle evaluates the option adopted and not the method of its adoption. In contrast, an agent applies a procedural principle to discover an act to perform. A rational procedure may culminate in an act that is not optimal. Rationality does not require calculating in all cases. In many cases, weighing pros and cons, computing utilities, and comparing all options is not a rational way to make a decision—spontaneity may be appropriate. A rational decision procedure takes account of circumstances. Brian Skyrms (1990), Ariel Rubinstein (1998), Gerd Gigerenzer (2000), Gigerenzer and Reinhard Selten (2000), Weirich (2004), and John Pollock (2006) pursue these themes.

Principles of rationality vary in the scope of their evaluations of acts. Some principles evaluate a decision for instrumental rationality, taking for granted the beliefs and desires that generate it. Others evaluate the beliefs and desires along with the decision. Principles of rationality also adopt conditions. A principle may evaluate a decision, assuming unlimited time and cognitive resources for reaching it. Idealizations play a crucial role by generating an initial theory with simplified principles of rationality. Relaxed idealizations later leads to more general principles and to a more realistic theory.

Principles of conditional rational also provide a way of putting aside mistakes. A person’s act may be rational given his or her beliefs, though his or her beliefs are mistaken and if corrected would support a different act. Evaluating his or her act for nonconditional rationality requires a complex assessment of the significance of the mistaken beliefs. Conditional rationality has an interesting structure resembling the structure of conditional probability. The rationality of an act given a background feature is not the rationality of the conditional that if the background feature holds then the act is performed. Nor is it the truth of the conditional that if the background feature holds then the act is rational.

Theoretical rationality treats belief formation, and practical rationality treats action. A theory of practical reasoning formulates rules of inference, leading to a conclusion that an act should be performed. It classifies reasons for acts and assesses their force. (For a survey, see Parfit 1984; Bratman 1987; Broome 2001; and Bittner 2001.)

Some arguments that degrees of belief should conform with the probability axioms point out that failure to comply leaves one open to a series of bets that guarantees a loss, that is, a Dutch book. This observation yields pragmatic reasons for compliance with the axioms. Some theorists hold that the probability axioms require a purely epistemic justification.

The principle to maximize expected utility uses probability, and so there are grounds for holding that probability is not purely epistemic and that its axioms do not need a purely epistemic justification. In contrast, probability’s role in assessing an option’s prospects requires that it represent only the strength of evidence. If it is sensitive to an agent’s goals, even cognitive goals, then using it to calculate an option’s expected utility counts the agent’s goals twice: one time in calculating the utilities of the option’s possible outcomes and a second time in calculating the probabilities of the possible outcomes. A purely epistemic justification of the probability axioms may be required given probability’s role in the calculation of an option’s expected utility. It may be required because of probability’s role as a guide to action.

Studies of rationality are multidisciplinary because several fields have a stake in their outcomes. Progress with theories of rationality is broadly rewarding, and many scholars are contributing.

RAWLS, JOHN
1921–2002

John Rawls was born in Baltimore, Maryland, in 1921. He received his BA in philosophy from Princeton in January 1943. He entered the army shortly after graduating from college and saw combat in the Pacific theater during World War II. After his discharge from the military, Rawls returned to Princeton, where he received his doctorate in philosophy in 1949. In that year, he also married Margaret Fox, to whom he remained married until his death. Rawls spent 1950–1952 as an instructor at Princeton and 1952–1953 on a Fulbright Fellowship at Oxford. Upon his return to the United States, Rawls joined the philosophy department at Cornell. He moved to the Massachusetts Institute of Technology in 1960 and to Harvard in 1962. Rawls remained a member of the Harvard faculty until he retired in 1991. He taught and published in retirement until ill health made it impossible for him to continue working. He died on November 24, 2002.

Rawls took the central problem of contemporary political philosophy to be that of framing a conception of justice that would be appropriate for liberal democracies existing under modern conditions. At the heart of a conception of justice, Rawls thought, are norms for distributing the "primary goods" generated by social cooperation and distributed by society's "basic structure." These goods are rights, liberties, income, wealth, opportunity, and the social bases of self-respect. The basic structure is the set of a society's most important economic, legal, and political institutions. In *A Theory of Justice*, Rawls defended two principles of justice governing the basic structure's distribution of these goods: (1) Each person is to have an equal right to the most extensive total system of equal basic liberties compatible with a similar system of liberty for all. (2) Social and economic inequalities are to be arranged so that they are both (a) to the greatest expected benefit of the least advantaged and (b) attached to offices and positions open to all under conditions of fair equality of opportunity.

Rawls defended these principles by arguing that they are the solution to an important choice problem. More specifically, he argued that they would be adopted in a version of the social contract that he called "the original position." In the social contract theories of Hobbes and Locke, the contract is arrived at in "the state of nature." Both Hobbes and Locke imagine this state to be one in which there is no government and in which human beings have God-given authority over themselves, but in which they also know that living under a common human authority would be advantageous. The choice problem confronting parties in the state of nature, according to Hobbes and Locke, is that of determining what form that authority should assume. Hobbes famously argued that parties faced with this problem would choose to delegate their powers to an absolute sovereign, while Locke defended limited sovereignty. In the original position, parties do not choose a form of government. Instead, they choose principles of justice to regulate their society. They choose from a menu of principles by asking which ones would guarantee them the greatest stock of primary goods if basic institutions conformed to them.

In the states of nature described by Hobbes and Locke, parties are free and are roughly equal in power. Despite their equality, they have information about themselves and their situation that they could, in principle, use to their advantage. In Locke's theory, for example, parties could know the extent of their property holdings, since Locke held that property rights are established before agreement on the terms of the social contract is reached. Differences in the parties' holdings could give some an advantage over others, and so parties' knowledge of differences in their holdings could affect the outcome of the contract.

According to Rawls's description of the original position, parties in it are deprived of all information about themselves and of all but the most general information about society. Given these restrictions on information, Rawls argued that it would be rational for parties in the original position to decide on principles using the maximin rule of rational choice. This rule enjoins choosers to select the option that guarantees the best worst outcome. Applied to the original position, maximin enjoins parties to maximize the stock of primary goods they would enjoy if they were in the worst-off social position. Rawls argued that parties choosing in the original position, using maximin, would adopt his two principles. The first principle guarantees equal liberty. The second clearly imposes a strong restriction on economic inequality and requires that all have equal opportunities to secure positions of advantage. Equality of opportunity, in turn, requires far
more than the absence of legal barriers to such positions. Rawls believed that social and economic class of origin should not affect life prospects. Fair equality of opportunity therefore requires systems of education and training sufficient to ensure that developed talents are widely dispersed. Equal liberty has long been a part of the liberal tradition. Part of Rawls's own pioneering contribution was to show the resources of the social contract tradition could be deployed to defend equality of opportunity and highly economic egalitarianism as well.

The lack of information available in the original position, effected by what Rawls called “the veil of ignorance,” struck many rational choice theorists as an implausible stipulation. Rawls defended the informational constraints by arguing that the veil of ignorance merely makes vivid a condition we intuitively recognize as a plausible one to impose on our own reasoning about justice: Our thinking about what is right should not, we think, be distorted by information about what is to our own advantage. The veil of ignorance guarantees that the parties' reasoning about justice will not be distorted in this way. Because parties in the original position are free, equal, and unbiased, Rawls argued, they are situated fairly. Because they are situated fairly, he concluded, the principles they would choose are fair. Rawls therefore called his conception of justice “justice as fairness.”

Modern liberal democracies exist under conditions of religious and philosophical pluralism. In Political Liberalism and other later work, Rawls argued that justice as fairness could secure agreement about basic justice among citizens of democracies in these conditions. It could do so because justice as fairness does not begin with metaphysical theses about the human person or the human good that are drawn from any one religious or philosophical view. Rather, it begins with ideas about the person, about political argument, and about social cooperation that are implicit in the public culture of democratic societies. For example, Rawls argued that the conditions of the original position “represent” fundamental elements of human moral personality. Rawls's argument that political philosophy should begin with ideas latent in public culture seemed to some philosophers to introduce a highly questionable method into political theorizing. But, Rawls countered, liberal thinkers in the early modern period sought a basis for political agreement that could be shared by citizens of diverse religions. To claim that political philosophy should not presuppose the truth of a contentious metaphysical theory is to do no more, he maintained, than to extend their principle of toleration from religion to philosophy itself. Because the principle of religious toleration is so much a part of the liberal tradition, Rawls's imaginative extension of the principle of toleration—like his defense of economic egalitarianism and fair equality of opportunity—counts as an important part of his enduring bequest to that tradition.

REACTANCE THEORY

Research in social influence demonstrates that individuals often move in the direction demanded by a leader (obedience) or modeled by a majority (conformity), and cognitive dissonance theory suggests that individuals will depreciate the items and activities that are denied them (“sour grapes”). However, despite the allure of cognitive consistency and the power of the leader and majority, there are many cases in which people resist influence and even move in the opposite direction (“boomerang”). American psychologist Jack Brehm's (1966; Brehm and Brehm 1981) theory of psychological reactance offers an explanation for this obstinate behavior and identifies the conditions under which individuals will be motivated to resist compliance.

Brehm argues that individuals have a set of “free behaviors” that they believe they can engage in at present or some time in the future. Behavioral freedoms vary in importance, with some being highly important because they deal with critical survival. Stephen Worchel (2004) suggested that these freedoms help define the individual's self-identity, and many are based on the positions one holds in groups. Jack Brehm and Sharon Brehm (1981) argued that these freedoms help establish the individual's sense of control over his or her environment. Events that threaten or eliminate behavioral freedom create a motivational state (reactance) aimed at restoring the freedom(s) in question. The degree of reactance is determined by the importance of the threatened/eliminated freedom(s) and the degree of threat. A threat or elimination of freedom results in an increase of attractiveness of the forbidden act.
Reactance Theory

and the motivation to engage in that behavior. Hence, pressure to engage in a specific act may arouse reactance because this pressure threatens the individual's freedom to adopt other positions or engage in other behaviors. The result will be an increase in the motivation to embrace the forbidden alternative.

For example, Thomas Hammock and Brehm (1966) led children to believe that they could choose between a number of candy bars. When the experimenter threatened the freedom to choose candy bar X by stating that candy bar X should not be chosen, children reacted by choosing the item. In another situation, the importance of the freedom to play with a toy was varied by pairing it with a similar type of toy (low importance) or a different type of toy (high importance). The degree of threat to play with a specific toy was manipulated by placing it behind either a high barrier (high threat) or low barrier (low threat). The combination of high importance and high threat increased the likelihood of children choosing the toy behind the barrier (Brehm and Weinraub 1977). And Worchel and Brehm (1970) found that a target audience was more likely to adopt a forbidden position (boomerang) when the communicator threatened their freedom by explicitly telling them that they could not adopt this position.

Reactance theory has also been applied to explicate findings in a variety of other areas. For example, the empirical foundation of cognitive dissonance theory was research demonstrating that after choosing between two relatively attractive items, individuals enhanced the attractiveness of the chosen item and depreciated the rejected item (Brehm 1956). However, closer inspection of the behaviors in this free-choice paradigm reveals that prior to the decision individuals often pay closer attention to the item they eventually reject, and immediately after the choice the rejected alternative increases in attractiveness and the chosen alternative's attractiveness decreases (regret). These effects have been explained by suggesting that choosing an alternative eliminates the freedom of the individual to have the rejected alternative, thereby creating reactance.

In another realm, research has demonstrated that an item (a commodity or individual) becomes more attractive when it becomes more scarce, distant, or difficult to obtain. Each of these conditions can be viewed as threatening the individual's freedom to possess the item and as arousing a state of reactance. Similar reasoning has been applied to explain why censored material is often more desired and influential than material readily available to the individual. Other research has shown that an individual's freedom may be threatened when he or she observes the freedom of a closely related group member being threatened (implied threat), and freedom may be restored (implied restoration) when the individual observes a group member regaining his or her freedom (Worchel and Brehm 1971). In a unique twist, reactance theory has been applied to explain why desired behavior change in therapy settings may be achieved by discouraging the desired behavior (paradoxical intervention), and to caution health communicators about overly strenuous efforts to dissuade an audience from engaging in risky behaviors (e.g., the use of drugs, unprotected sex) that audience members view as important.

Overall, reactance theory points out that for every force pushing in one direction, there will be a counter-force moving people away from this position. The counter-force will be strongest when a negated position (or behavior) is perceived as important and as comprising a free behavior.

There are two universal principles regarding the readiness of children for formal education. They are (1) that children will learn most effectively if they have certain personal characteristics, and (2) that teachers must adjust their instruction to accommodate those features. Many lists of the specific factors that constitute children’s readiness for conventional instruction have been drafted. These tallies include, among other things, children’s interest in books and reading, their fondness for conversation, curiosity about the world, and the quality of their oral language, including the extent of their knowledge of the meanings of words.

Also included on these lists are youngsters’ emotional, psychological, and physiological characteristics, how well they function socially, and the economic status of their families. The last factor is considered to be especially important: Children in low-income families frequently suffer not only from a lack of the necessities of daily life, but also from inattention from their parents. Aggravating this situation is the fact that parents of such children often are not married. It is found at all socioeconomic levels that children raised in married, two-parent families display greater readiness for formal education than do youngsters brought up by single parents.

In the United States an educational program called Head Start was established in 1965 to benefit four-year-old children from low-income families. A major assumption of Head Start is that many children have handicaps to learning due to deficits in the culture of poverty, which encompasses issues such as substance abuse by parents, homeless families, little if any family health care, lack of prenatal care for mothers, neighborhood crime, and the relatively large number of children in foster care. Head Start programs have not always succeeded in one of their main goals: to raise children’s later standardized academic test scores. However, there are indications that children’s attendance in Head Start classes produces other favorable results such as greater social maturity, a higher rate of high school graduation, fewer absences from school, greater self-esteem, and more positive aspirations for life. As a consequence, Head Start has not lost any significant financial support from the U.S. federal government.

There also is widespread recognition that all children need to be ready to perform adequately in grades one through high school. Students who display significant difficulties in learning at these grade levels usually are enrolled in small-sized “special education” classes, which acknowledge that some students are not able to take advantage of regular school offerings, and that teachers must be prepared to help them overcome specific handicaps to learning that they have either inherited or developed. There is disagreement about the most time- and cost-effective methods for teaching these students. The two most prevalent special-education teaching methods are the academic skills and knowledge approach and the child-centered method.

Advocates of the former insist that students’ acquisition of discrete academic knowledge and skills must be the paramount goal of schools. Hence, they argue for “direct, systematic, intensive, early, and comprehensive” (DISEC) instruction of a prearranged hierarchy of discrete scholastic skills and knowledge. This view assumes that some students enter schools without having mastered the standard English grammar that is considered to be necessary for them to become effective learners. Under the DISEC method, children’s knowledge about basic academic subject matter and skills, sometimes called “cultural literacy,” is developed in as interesting a manner as possible. This itself is not a controversial position, but the kind of learning assessment favored by DISEC teachers of children’s learning has been disputed. Most DISEC teachers strongly defend standardized tests designed to measure students’ subject matter knowledge and their mastery of standard English grammar.

Teachers who oppose DISEC instruction conduct their classes in a very different way. Their first action is to determine what children are interested in learning. If a given subject matter is found to be meaningful to children, it will be selected for their further attention. In addition, individual children are allowed to pursue queries that excite their particular fancies. A goal of the non-DISEC teacher is to develop children’s abilities to explain and find solutions for everyday dilemmas. In these classes the conventional skills of reading, spelling, handwriting, written composition, speaking, and listening are taught only when they are needed to aid a student’s process of solving problems. The traditional subjects science, history, geography, mathematics, literature, art, and drama also are only engaged by students when and if they are deemed useful to finding solutions to questions that they themselves have decided to resolve. Also, non-DISEC teachers usually honor nonstandard-English spoken dialects as valid and legitimate idioms.

Non-DISEC teachers generally are strongly opposed to the administration of standardized tests of students’ academic skills and knowledge because these tests do not measure the kinds of skills and knowledge their pupils acquire from problem-solving activities. Thus, whereas DISEC teachers view standardized tests as allies in their instructional endeavors, non-DISEC teachers declare them to be unacceptable because they hold all students to uniform standards of learning.

Teachers opposed to DISEC instruction also often deplore what they consider to be unnecessary stress on children to regulate their mental behavior at earlier and
earlier ages. In this respect, they voice doubts as to the merits of the conventional homework that younger students ordinarily are required to complete. Traditional homework exercises are deemed an unsatisfactory substitute for children’s free play, the exercise of their creative imaginations outside of school, and intimate interactions with their parents. Both positive and negative findings about the merits of homework have been reported.

Children's readiness for schooling is a complex matter, and educators still hold strikingly contradictory viewpoints on the subject. Confounding the issue is the fact that empirical as opposed to subjective evidence about it often has been contradictory.

REAGAN, RONALD

1911–2004

Ronald Wilson Reagan, the fortieth president of the United States, held office from 1981 to 1989. Reagan was born in Tampico, Illinois, on February 6, 1911. In 1937 he started a thirty-year career in film and television, and his time in Hollywood engendered his interest in politics. Upon leaving military service at the end of World War II (1939–1945), Reagan was an active member of the Democratic Party and had been a supporter of U.S. presidents Franklin Roosevelt (1882–1945) and Harry Truman (1884–1972). Newly out of uniform, he engaged in union activity with the Screen Actors Guild and was its president for six years. Reagan’s experiences of the postwar red scare in the movie industry during the heyday of McCarthyism worked to solidify his staunch anti-Communist orientation. In 1952, owing to the new trajectory of his career and accompanying events, Reagan publicly renounced his Democratic Party affiliation and became a conservative Republican. His extensive acting experience, his service as president of the Screen Actors Guild, and his tenure as public spokesman for General Electric all prepared Reagan well for his entrance into California politics as state governor, and then beyond onto the national stage. Reagan’s political style is noted for his ability as a highly effective public speaker and his successful use of the presidential pulpit to advance his policy agenda, skills that earned him the moniker of “the great communicator.”

At the age of fifty-five, Reagan defeated the Democratic incumbent and was sworn in as California governor in 1967. He was reelected in 1970. His tenure as governor was marked by his sensitivity to the need to compromise his conservatively driven policies so as to allow enactment of legislation, as well as his management style of delegation and decentralization. Reagan’s aides exercised great authority and served as important formulators of policy, a management orientation that later marked his presidency and would be criticized subsequently as excessive abdication by Reagan of his presidential responsibilities. In the late 1960s, he took a firm and aggressive stance against student protesters at colleges, most notably at the University of California at Berkeley in 1969, by calling in the national guard and state police to deal with demonstrators.

Reagan secured the Republican presidential nomination in 1980 and chose George H. W. Bush as his vice-presidential running mate. Reagan’s campaign stressed the economy, governmental growth, the budget deficit, declining U.S. prestige abroad, and the threat of the Soviet Union. Winning the presidency with 51 percent of the popular vote and 489 electoral college votes, Reagan took office with a new Republican majority in the Senate but with a House of Representatives controlled by Democrats. In 1984 Reagan won reelection with a landslide victory over Democratic opponent Walter Mondale, obtaining a record 525 electoral votes and 59 percent of the popular vote.

The first year of Reagan’s presidency is regarded as his most significant domestically. After recovering quickly from an assassination attempt in early 1981, Reagan advanced his supply-side economic policies through Congress. Showing political skill, he was able to get congressional enactment of sweeping tax reductions that were designed to induce economic growth. Congress passed most of the president’s proposals, including a cut in income-tax rates, a substantial increase in defense spending, and a drastic shrinking of nondefense, social-welfare expenditures. The purpose of these policies was to drive economic growth, and the resulting increase in governmental revenue via taxes was expected to offset the deficit and produce a balanced federal budget. The actual results were not as envisioned: Tax cuts and defense spending
pushed the United States into becoming the world's biggest debtor nation, and the federal budget deficit and national debt exploded. Reagan did, however, preside over the longest peacetime economic expansion in American history.

With a Republican-controlled Senate, Reagan effectively and efficiently used his judicial appointment power to advance his conservative social agenda at all levels of the federal judiciary by nominating only "the ideologically faithful." By the time of his departure from the White House in 1989, Reagan had appointed over 60 percent of all federal judges and four U.S. Supreme Court justices, a highly significant legacy.

In foreign affairs, Reagan's stern anti-Communist posture in his first term evolved into one of relative conciliation and rapprochement in his second term. His building of a line of communications with the new Soviet leader Mikhail Gorbachev through several summit meetings was pivotal in the reduction of tension between the two superpowers. This development ostensibly ushered in a new era of U.S.-Soviet relations. In addition, Reagan successfully enhanced American power in the international arena through a military buildup and the use of force in selected regional conflicts.

Reagan will be particularly remembered for bringing forth a new tide of conservatism to American politics. Domestically, Reagan changed the face of campaigning and governing with effective imagery, symbols, and video. He emphasized personal warmth and charisma, and forged success through economic growth, tax cuts, and tax reform. His legacy has been tempered by his administration's long-term budget deficits and national debt concerns, and by the Iran-Contra scandal, in which presidential aides violated federal law in an effort to advance foreign policy endeavors that Congress had prohibited. Many of the tenets of Reagan's 1980 campaign, including reducing the size and scope of government and balancing the federal budget, were not achieved.

Reagan left office in 1989. He was diagnosed in 1994 with Alzheimer's disease, a condition typically associated with the elderly in which the mental capacity and intellectual functions decline due to deterioration of brain cells. Some analysts assert that early signs of this illness (such as memory troubles) could be observed while Reagan was still in office, but this is a point of contention and speculation. Ronald Reagan passed away at his home in Los Angeles, California, on June 5, 2004. He remains a revered figure in the Republican Party and among adherents of conservative ideology.

Stephen R. Routh

**REAL INCOME**

Many societies strive to improve the well-being of their members by increasing their incomes. But an increase in one's income (wage, pension, and so forth) does not necessarily mean that he or she is better off unless inflation is appropriately factored in. This is because inflation reduces purchasing power, the amount of goods or services that one can afford with a given amount of income, thus eroding some or all of one's nominal income gains. In order to make an accurate assessment of the effect of an income change on well-being, it is important to consider real income (income in constant dollars), which takes inflation into account, instead of nominal income (income in current dollars), which does not.

**MEANING AND ORIGIN OF THE CONCEPT**

Real income of a particular individual or household is the income that is adjusted for the effects of inflation on purchasing power. To see the rationale for inflation adjustments, suppose that your nominal income increases by 50 percent (from $200 to $300) this year over last year, but the price per bottle of your favorite drink increases by 25 percent (from $2.00 to $2.50) over the same period. With last year's lower income ($200) you could afford $200 / $2.00 = 100 bottles of the drink at that year's price ($2.00). With this year's higher income ($300), you can afford $300 / $2.50 = 120 bottles of the drink, which is more than the 100 bottles you could afford with last year's income, indicating that you are better off (i.e., your real income has increased). However, if the price of a bottle of the drink increases by 100 percent (from $2.00 to $4.00), you can afford $300 / $4.00 = 75 bottles of the drink with this year's higher income ($300) at this year's higher price ($4.00), which is less than the 100 bottles you could afford with last year's lower income ($200) at last year's lower price ($2.00). Hence you are worse off this year relative to last year, even though your income has increased, because your real income has decreased. You are better (worse) off if the percentage increase in your nominal
income is greater (less) than the percentage inflation rate because the percentage growth in your real income (i.e., the percentage growth in your nominal income minus the percentage inflation rate) is positive (negative). A fall in your nominal income does not necessarily imply that you are worse off as long as the percentage decrease in the price level is higher than the percentage decrease in your nominal income, because the percentage change in your real income is positive. In summary, you are better off as a result of an increase or decrease in your nominal income provided that the percentage change in your real income is positive. If the inflation rate is positive, doubling nominal income this year over last year will less than double the corresponding real income. If the inflation rate is zero, however, doubling nominal income also doubles the corresponding real income.

Real income could be viewed in two equivalent ways. Again suppose that your nominal income rises by 50 percent (from $200 to $300) this year over last year but the price per bottle of your favorite drink rises by 25 percent (from $2.00 to $2.50) over the same period. First, with the $200 you could afford $200 / $2.00 = 100 bottles of the drink at last year’s price ($2.00). However, to buy the same 100 bottles of the drink at this year’s price ($2.50), you require $250. Because your income has increased from $200 to $300, your real income has increased by only $300 – $250 = $50, a 25 percent increase from your original income of $200 last year (i.e., less than the 50 percent increase in your nominal income). Second, because your nominal income increases by 50 percent (from $200 to $300) and the price of the drink increases by 25 percent (from $2.00 to $2.50), your real income increases by 50 – 25 = 25 percent, which also amounts to $50.

Real income is relevant in wage contract negotiations. An important goal of unions is to protect the real wages of their members. Achieving this goal involves determining the appropriate amount of nominal income adjustment that would protect union members’ real incomes in inflationary situations. To demonstrate the adjustment process, suppose that your nominal wage increases from $50,000 to $52,000 this year over last year, but the price of a given basket of goods and services that you buy increases by 10 percent. With the 10 percent price increase, you would require $50,000 × 1.10 = $55,000 this year to afford the same basket as last year. Because your new nominal income is only $52,000, your real income will have decreased by $55,000 – $52,000 = $3,000, which is 6 percent lower than your nominal wage of $50,000 last year. This can also be confirmed by noting that the percentage increase in your nominal wage from $50,000 to $52,000 is 4; the percentage increase in the price level is 10; hence the percentage increase in your real wage is 4 – 10 = –6, indicating a 6 percent decrease in your real wage. To maintain the same real income, your nominal income has to be increased (or indexed) by 10 percent, the same as the inflation rate (i.e., from $50,000 to $50,000 × 1.1 = $55,000). The same principle is used to index pensions, welfare allowances, and other incomes in order to maintain desired real income levels. In general, if real income decreases by, say, 5 percent, nominal incomes must be increased by 5 percent in order to maintain the same real income as before.

As noted above, adjusting nominal income to maintain some desired level of real income requires information about the inflation rate. However, practical difficulties arise in the measurement of inflation. In practice, the inflation rate is computed from a price (or cost-of-living) index, a summary measure describing relative price changes between some reference (base) period and another (current) period. For purposes of indexing wages, pensions, and so on, the inflation rates are commonly derived from a Consumer Price Index (CPI). The CPI is based on the prices of a representative “basket of goods and services” purchased by households. The economists M. C. McCracken and E. Ruddick (1980) provide a simple exposition of the nature and practical difficulties associated with CPI as an inflation measure. The economic statistician Roy Allen (1975) describes some applications of price index numbers in the measurement and international comparisons of real incomes. Given the aforementioned connection among real income, prices, and purchasing power, the origin of the real income concept can be linked to that of price index numbers, which the economic statistician Wesley Mitchell (1938) traced as far back as the 1700s.

The concept of real income is used in national income accounting to refer to real gross domestic product (GDP), the real value of all final goods and services produced in a country during a specific time period. In evaluating real GDP, the output for different years is evaluated using a common set of prices, thus eliminating the contamination of the value of actual output by inflation. Real GDP is obtained by deflating nominal GDP by a special price index called the GDP deflator, which measures changes in the average price of a broader “basket of goods and services” than does CPI. The usage of real income to mean real GDP is commonplace in the literature on economic growth and the measurement of human well-being, among others.

REAL INCOME AS A MEASURE OF WELL-BEING
Because real income takes into account the actual physical quantity of goods and services that can be consumed with the income, it is a better measure of human well-being than its nominal counterpart. It is therefore not surprising
that real income has been incorporated into several measures of human well-being developed by the United Nations Development Program (UNDP) in its annual issues of the Human Development Report. UNDP (2006) describes these measures, including the Human Development Index (HDI), the Gender-Related Development Index (GDI), and two human poverty measures (HPI–1 and HPI–2).

Amartya Sen, winner of the 1998 Nobel Prize in Economics, has raised some philosophical issues surrounding the appropriateness of real (or nominal) income as a measure of well-being. Sen (1985) argues that functional capabilities (i.e., what a person can do or can be) are more important than income improvements. This view, which has come to be known as the “capabilities approach,” emphasizes the removal of obstacles to what a person can be or can do. Such obstacles include illiteracy, poor health, lack of access to resources, and lack of civil or political freedom, among others. The ideas underlying the capabilities approach have been incorporated in UNDP’s human development and poverty measures.

The link between real (or nominal) income and happiness has been the subject of empirical investigations by economists and sociologists. There is evidence that higher incomes may not necessarily translate to greater happiness. The economist Mathias Binswanger (2006) has reviewed several explanations for the failure of (real) income growth to increase happiness.

REALIGNMENT

SEE Dealignment.

REALISM

Realism as a nameable phenomenon in Western thought and culture emerged in France during the mid-nineteenth century. Primarily a movement in art and literature, it claimed to represent common people and their everyday circumstances based on accurate observation. Realism challenged centuries of tradition, when the highest art aspired to idealized pictorial forms and heroic subjects. Supporters of realist art considered its veracity to be an indication of an artist’s “sincerity,” a moral judgment. It acquired a democratic political dimension from its inclusiveness and from the accessibility of its imagery to ordinary people unversed in the classics but capable of recognizing “truth.” These appeals were informed by progressive attitudes and an empirical concept of knowledge, as in the social theories of Pierre-Joseph Proudhon (1809–1865) and the scientific epistemology and the positivist philosophy of Auguste Comte (1798–1857). The leader of artistic realism was the French painter Gustave Courbet (1819–1877). Its advent revolutionized the history of art, leading to impressionism. In literature, various writers represented realism, from Gustave Flaubert (1821–1880) to Henry James (1843–1916). Unlike in art, literary realism was rarely self-conscious or polemical.

The movement realism must be distinguished from the generic term realism—the latter an aspect of much art and literature throughout time. In its general meaning, the word can refer to an optical or descriptive realism, in which forms or details appear to be drawn from life or produce an illusion of reality. In art, this type of realism is an ingredient in the high classicism of the Greek age of the Parthenon, in Roman portraiture, in certain Renaissance and Baroque styles, in Pre-Raphaelitism, and in photorealism, among many others. In literature, it is an aspect in certain passages of Homer’s Iliad, in the early novel generally, and in the provincial settings of Honoré de Balzac (1799–1850) or the urban settings of James. Indeed, in literature, prose generally developed as a realist genre, as opposed to epic or lyric poetry. In theater, realism was associated primarily with comedy, whereas tragedy was considered more ideal. Following a related hierarchy, real-
Realism

ism in art developed in opposition to academic classicism, which looked back to antiquity and the conventions of the French classical theater of Pierre Corneille (1606–1684) and Jean Racine (1639–1699) for its idealist forms.

The realism movement was a response to two interrelated factors. On the one hand, there was an increasing demand for rational and eventually scientific empiricism, which since the Enlightenment had been regarded as intellectually and socially progressive. The invention of photography in 1839, which introduced a new standard for optical realism, can be considered in the light of the same spirit, for there would otherwise have been no incentive or use for it. Second, the same rationalism encouraged the rights of the individual against both coercive political regimes and their art academies. Realism represented a rebellion, said to be grounded in “truth,” against academic recipes and conventions. When Courbet’s paintings of 1849 to 1855 made such attitudes militant, he adopted the term realism, which was being used by both his critics and supporters. A later term, naturalism, was developed as a more scientific-sounding, less-politicized alternative by the French novelist Émile Zola (1840–1902) and the art critic Jules Castagnary (1830–1888).

Realism’s most coherent artistic manifestation occurred in mid-nineteenth-century France. It followed romanticism, which was already encouraging artistic freedom and self-expression, with artists looking to nature as their source. In his Realist Manifesto (1855), Courbet stated his aim as: “to translate the customs, the ideas, the appearance of my epoch according to my own appreciation” (Rubin 1997, pp. 157-158). Linking a faithful portrayal of his times with artistic independence (from teachings based on imitations of classical art), he made both elements the basis for the movement of which he became the undisputed leader. In the 1840s, Courbet’s generation drew on two related artistic trends. First was the Barbizon school of landscape painters, who studied people and places from a recognizable countryside, usually near Paris. Second was the recent popularity in literature and art of rural and provincial life. As a contrast to urban materialism and its inequities, the virtues and innocence of country folk were extolled in novels by George Sand (1804–1876) and stories by Courbet’s friend Champfleury (Jules Husson, 1821–1889). Painters like the Leleux brothers and Jean-François Millet (1814–1875) embodied this ethos in their representations of peasants. In addition, simple, often crude folk art and poetry were admired as naïve expressions of popular culture and the working class.

The difference between Courbet and these artists was that, beginning with his Stonebreakers (1849), destroyed during World War II, the people, places, and activities in Courbet’s paintings appeared specifically contemporary, devoid of antimodern nostalgia, whereas his predecessors evoked a timelessness associated with romantic innocence and virtue. Courbet’s workers alluded to the harsh conditions of the 1840s, when failing harvests drove many off the land into day-wage labor, providing raw materials for modern roads, railroads, housing, and industry. A Burial at Ornans, painted in 1850, showed a ceremony outside Courbet’s hometown in the region of Franche-Comté near Switzerland. Against their rugged landscape, some thirty odd friends and neighbors gathered at the open grave of a respected citizen. Courbet portrays death as a prosaic, literally “down-to-earth” event whose meaning goes no further than laying the body in the ground. The huge canvas with life-sized figures flaunted Courbet’s challenge to assumptions about what was worthy of large-scale artistic representation, and his ostensibly coarse technique evoked a worker’s handicraft. Combined with their ostensible politics, the lower-class content and unrefined surfaces of his paintings caused a scandal. In 1855 Courbet challenged authority in a solo exhibition outside the grounds of the Universal Exposition. The central painting in his “Realist Pavilion” was The Studio of the Painter, in which he showed himself at the easel, supported by friends on the right and facing on the left a mix of figures embodying various ideas he considered outdated. The purpose of this much-interpreted painting was a declaration of both artistic freedom and solidarity with his own community.

Similar scandals shook the realm of literature. Earlier in the nineteenth century, Stendhal (Henri Beyle, 1783–1842) began the study of contemporary manners as a way to expose hypocrisy. In 1856 and 1857 respectively, Flaubert and the poet Charles Baudelaire (1821–1867) were brought to trial for offending public morality. Flaubert’s novel Madame Bovary (1856) was about an adulterous housewife bored by her conventional husband. Poems from Baudelaire’s Les Fleurs du Mal (1857) were often set in contemporary Paris and sometimes described erotic experience in a highly suggestive manner. A decade later, Zola considered his own novels analytic. In a preface to his notorious murder story Thérèse Raquin (1867), he compared his way of representing subjects—an adulterous woman and her lover plotting to murder her husband—to the scientific analysis performed by surgeons in medical dissections. In his art criticism, Zola’s interpretation of the painting of Édouard Manet (1832–1883) was similar. Calling Manet a child of his times, in which the direction was toward positivism, Zola praised the artist’s Olympia (1863–1864), a painting of a naked prostitute that was obviously meant to shock. Zola wrote that this picture, drawn from modern life, was sincerely observed by a dispassionate artist whose sole interest was to observe forms, colors, light, and shade.
Realism was associated with impressionism when the latter first appeared, since impressionism took up the commitment to modern life and contemporary manners flaunted by Manet and the contemporary novel. The young Claude Monet (1840–1926) was friendly with and drew upon Courbet and his technique, as did several other impressionists. Their imagery ranged from sailboats, promenades, and other forms of modern leisure to representations of industrial riverbanks, railroads, and factories. But the greater legacy of realism was to free artists to paint “sincerely”—that is, from their personal vision, which they indicated by a highly individualized style, often loosely handled as if the performance of representation were as important as the subject matter being painted. Hence, impressionism, praised by many for capturing the reality of a fleeting moment, contained the seeds of the demise of realism. The artifice of its execution was in constant tension with its illusion of the real. Yet realism successfully undermined doctrinal academicism once and for all by legitimizing images of modern life, heroic or anecdotal, rural or urban, and painted in whatever way the artist chose. It even entered sculpture, though as a more literal medium sculpture was far less challenging to traditional modes of representation than was painting, until the liberties with form taken by the “impressionist” sculptor Auguste Rodin (1840–1917).

Russian linguist Roman Jakobson (1896–1982) theorized that at the core of realism in art and literature is metonymy, a mode of figuration in which the part stands for the physical whole. The metonym is opposed to metaphor, in which an object stands for an idea; it is, in other words, a wholly concrete means of expression. Roland Barthes (1915–1980), in his famous short essay “The Reality Effect” (1968), pointed out that a profusion of observed detail in the realist novel slows the narrative, making it seem to advance almost unnoticeably, as if in real time, and making it appear to be the result of the concrete context established by such extensive description. In realist and impressionist painting, a sense of materiality and a dispersion of interest were achieved by a profusion of detail and a fragmentation of form across the entire image, along with subject matter from everyday modernity. Such painting was often compared to photography, the latter considered no more than a mechanical exercise, devoid of imagination and creativity. Painting was expected to emphasize certain truths in order to uplift and educate its audience, whereas photography’s lack of selectivity made the edges of a composition as interesting as the center and seemed to negate the possibility of moral content.

The response to realism by establishment artists was to employ their labor toward a finished optical realism, as in the work of Léon Bonnat (1833–1922), or to incorporate occasional free paint handling, as did Jules Bastien-Lepage (1848–1884). In other countries, realism reinforced existing trends in genre painting, as occurred in Holland (e.g., Jozef Israëls [1824–1911]) and England. The macchiaioli movement in Italy paralleled realism and impressionism, especially in outdoor scenes. Verismo in opera followed later, near the turn of the century. In Germany, where Courbet was popular, realist images acquired a grander scale and avant-garde technique, as seen in the work of Wilhelm Leibl (1844–1900) and Max Liebermann (1847–1935). Artists in the United States adopted realism, as exemplified by Thomas Eakins (1844–1916), then impressionism, as national styles, although usually without the avant-garde connotations. Later realisms, such as in Richard Estes’s displays of photograph-like technique or Eric Fischl’s suburban psycho-realism, were often ostentatious. Even in politics, first with Klemens von Metternich (1773–1859) in Austria, then with Willy Brandt (1913–1992) in Germany, there emerged a so-called realpolitik that looked to facts on the ground rather than ideology for its goals. Whatever its manifestations, then, realism continues to have a grip on consciousness thanks to its claim to represent “reality” truthfully, compared to forms of thought that defy material verification.

**REALISM, EXPERIMENTAL**

Experimental realism refers to the extent to which an experimental manipulation actively involves the participants in the research. If the manipulations are realistic, the phenomenology of the participant will be like that of a person in the social circumstance being indexed by the manipulation even if the lab circumstance is quite different than the naturalistic one. Thus, the goal of developing
realistic experimental manipulations is to have participants really experience whatever psychological states the experimenters are interested in studying in the context of the conditional variations that might instantiate those states. To the extent that the participant is made to take the experiment seriously they will be more likely to be influenced by the manipulations.

The general logic of the experimental method in research is based on the detection of causal relationships. An independent variable is manipulated in a controlled environment, with the intention of assessing how the changes in the independent variable influence the dependent variable. Therefore, by controlling for other possible influences, an experiment can help determine whether changes in the independent variable cause changes in the dependent variable. It is important for the manipulation of the independent variable to be strong enough to have the desired effect on the participants. If the experimental manipulation does not actively involve the participants, the resultant experiment is not an accurate test of the causal relationship between the independent and dependent variables.

ISSUES OF VALIDITY

If an experiment lacks experimental realism, the participants are not affected by the manipulation of the independent variable. Thus, researchers’ efforts to maximize a study’s experimental realism are important in ensuring the construct validity of an experiment. Construct validity refers to the effectiveness of experimental manipulation. A study is high in construct validity when the manipulation produces the intended changes in the conceptual variable. When the variables in an experiment truly represent the abstract, hypothetical variables of which the researcher is interested, the study is said to possess a high level of construct validity.

The issue of validity is often used to critique experimental designs. It is sometimes difficult for researchers to defend their experiment and show that their study was high in experimental realism. One way to measure the extent to which participants were actively involved in the psychological processes engaged by the research is to use manipulation checks. A manipulation check involves measuring whether the participants actually experienced different levels of the independent variable. This serves to provide a test of whether the study had adequate experimental realism. That is, did the participants believe the manipulation?

RESEARCH PROCEDURES

It is difficult to specify exactly what makes a study high in experimental realism. The experimental design typically involves the use of some deception. This is because the researcher needs to create a convincing illusion in order to have participants become engaged in the manipulation of the independent variable. It is generally advised that a researcher create a manipulation that is as strong as possible, within the confines of ethical and practical concerns. This ensures that the manipulation is maximally effective, thereby increasing the experimental realism of the study.

Even if explicit deception is not used in the experimental design, the researcher will often misinform the participants about the true purpose of the experiment. This involves what is referred to as a “cover story,” where the researcher describes the purpose of the study to the participant using a believable but fake explanation. This serves to get participants into the right frame of mind for the purposes of the experiment, while ensuring that participants will not know the true purpose of the study and behave in a certain manner simply because it is what the experimenter expects.

One famous psychological experiment, conducted by Stanley Milgram in 1974, relied on deception to achieve experimental realism. In this experiment of obedience, participants were led to believe that they were taking part in a study of the effects of punishment on learning and were asked to deliver strong electric shocks to a fellow participant whenever he failed to learn an association between two words. As the intensity of the shock the participant ostensibly delivered to the learner increased, and the learner began to complain of a heart condition, participants often questioned the method or protested the use of such strong shocks. The researcher would always respond in the same manner, assuring the participant that the learner would not suffer any permanent damage and that the integrity of the experiment required that he continue with the shocks. The true purpose of the experiment was to determine whether participants would obey the instructions of the researcher and continue to injure the learner even when they personally felt that it was wrong to do so. If participants had known the true purpose of the experiment, one can assume that they would not have continued to obey the experimenter. However, the deception used in this experiment allowed researchers to investigate the conditions under which participants will obey an authority figure that orders them to harm another person.

This strategy of using deception to minimize reactivity and response bias on the part of participants is a matter of ethical debate, since participants agree to take part in the research based on a fabricated explanation of the purpose of the experiment. However, the use of this deceptive practice is justified by researchers explaining that many questions cannot be meaningfully addressed in the context of an experiment without the use of deception, and that this practice results in minimal risk or harm to the participant. Indeed, after researchers explained the
true purpose of the experiment to participants in Milgram's experiment (in a process known as debriefing), most participants said that they understood why deception needed to be used in explaining the purpose of the study and that they did not regret participating.

Experimental realism is often discussed in contrast to mundane realism (also known as ecological validity). Mundane realism refers to the extent to which the research is conducted in situations that are highly similar to everyday life experiences. Experimental research designs often don't have high levels of mundane realism, since they are typically conducted in artificially created situations. However, even if the research situation doesn't look the same as an everyday situation, it can still feel like a real experience. That is the goal of maximizing experimental realism: to get an artificial experimental manipulation to feel like a real experience.

REALISM, MORAL
Moral realism is the doctrine that some moral claims are true in a way that is independent of their being endorsed, or regarded as true, by any human being. Consider, for instance, the claim that torturing babies for the sole purpose of deriving sadistic pleasure is immoral. Moral realists would regard this claim as true. But that itself does not distinguish the moral realist from many other moral theorists. What is distinctive about the moral realist is that the truth of this claim in no way depends on the attitudes that people take toward the claim itself. It is not true because one believes it or because society endorses it. For the moral realist, the standards that determine whether moral claims are true or false are as objective as those that determine the accuracy of claims in logic or the natural sciences.

All moral realists will accept that an action's rightness depends to some extent on the circumstances in which one is situated. That is because, for the realist, the correct standards of morality may well dictate different actions, depending on the circumstances. In some cases, for instance, it is morally acceptable to cut into the flesh of human beings—for instance, during surgery. But in other cases, such action is impermissible, because it is being done in the name of coercion or humiliation. What is centrally important for the moral realist is that attitudes about what is right and wrong do not determine what really qualifies as such. Even the most cherished moral beliefs might be mistaken, because their authority does not depend on an endorsement of them.

Moral realists qualify as cognitivists. Cognitivists are theorists who conceive of moral judgments in terms of their cognitive content and function. Cognitivists regard moral claims as capable of truth or falsity, and conceive of the function of moral discourse to be that of attempting to describe the nature of moral reality. This differs from noncognitivists, who consider moral judgments to be primarily expressions of emotions or commitments, and, thus, incapable of being either true or false.

Error theorists, like moral realists, accept cognitivism. But error theorists deny that there is any moral reality awaiting discovery. In rendering sincere moral judgments, one is indeed trying to state the truth about what is moral and immoral. But there is, according to error theorists, no such truth. Therefore, all fall into error when issuing moral judgments. Perhaps the most illuminating analogy here is that of the atheist, who regards theistic discourse as intended to describe an objective, divinely ordered reality. But, from the atheist's perspective, there is no such reality, and so all theistic discourse is riddled with error.

Moral realism should also be distinguished from ethical relativism. The relativist is also a cognitivist, and so believes that moral judgments are capable of truth and falsity. Unlike the error theorist, the relativist thinks that some moral claims are true. But they are true only because they accurately capture the implications of different social agreements. The realist and the relativist differ, in other words, on the ultimate source of correct moral standards. For the relativist, moral standards are correct because they are endorsed by various groups of human beings. For the moral realist, human endorsement is not the ultimate authority in morality.

In psychological circles, moral realism is often associated with the work of the Swiss psychologist Jean Piaget (1896–1980), who attributed a belief in it to very young children. In Piaget's hands, moral realism stands for the idea that there are objectively correct moral rules that are never permissibly broken, such that failure to adhere to them is always morally blameworthy. Neither of these latter implications is essential to the doctrine as it is currently discussed within the philosophical community.

REALISM, POLITICAL

Political realism is a view of politics that centers on power and conflict. The term goes back to the British historian E. H. Carr, who argued in 1939 that fact-driven “realism” needed to replace “utopian” trust in legal arrangements to preserve peace among nations. Unfamiliar to the liberal elites of America at the time, this view had a long tradition in European statecraft. Since the nineteenth-century, Germans had spoken of Realpolitik (realistic policy) and Machtpolitik (whose translation gave us “power politics”) in reference to a foreign policy that recognizes self-interest and power as the driving forces of international reality. Even older is the doctrine of “reason of state” (It. ragione dello stato, Fr. raison d’état, Germ. Staatsräson), which asserts that the state has principles of action of its own, allowing it to do what law and morality forbid to its subjects. (Since it acquired this meaning under the influence of Niccolò Machiavelli, the Florentine political thinker of the early sixteenth century, it is also known as “Machiavellism.”)

This type of intellectual reflection on power and politics goes back to the beginnings of political thought in the great civilizations of antiquity. In ancient Greece, for example, itinerant teachers of rhetoric and politics (known as sophists) argued during the fifth century BCE that morality is merely a convention (nomos) that stands in contrast to real human nature (phusis), which commands a ruthless struggle for advantage and the rule of the strong. This point was famously rendered by Thucydides in his History of the Peloponnesian War. In China, the legalist school (fa chia)—whose principal texts are the Book of Lord Shang and the Han Fei Tzu (written by the philosopher of the same name)—argued from the third century BCE onward that order required strict laws aimed at maximizing the power of the state and backed up by harsh punishments. In India, the tradition of arthaśāstra (science of material gain), especially the text attributed to Kautilya, who lived in the fourth century BCE, maintained that only the king’s “rod of punishment” prevented people from devouring each other in accordance with the “law of the fishes.”

Realpolitik, reason of state, Chinese legalism, and arthaśāstra are largely limited to providing practitioners of politics with maxims of action, such as punishing small infractions harshly so that big ones will not arise, or dividing one’s enemies to defeat them one by one. Political realism contains these maxims, but it also relates them in theoretical fashion to assumptions about human nature, morality, and the world at large. Its generative logic was stated most cogently by Machiavelli and the seventeenth-century English philosopher Thomas Hobbes. Human beings, by nature, fear each other on account of their capacity to inflict harm and their uncertainty of each other’s intentions. To secure themselves, they acquire enough power to deter or, even better, subdue the others.

From this nature arises a general struggle for power, which is aggravated by the fact that people want not only security, but also glory, power, and wealth. In addition, they will readily commit acts of aggression to attain these things. As the weak are forced to submit to the rule of the strong, political units (e.g., tribal chiefdoms, ancient city-states, feudal kingdoms) arise, providing a measure of protection and prosperity in exchange for obedience. But they cannot maintain order without repeatedly injuring innocents, which is morally warranted by the good consequences that order has for the others. Moreover, force and fraud continue unabated in the relations between units (that is, in their foreign affairs). Hence, the world is not a coherent ethical order, as the classical and Christian traditions maintain, but a chaos of conflicting ends and calamitous accidents.

Political realism became one of the major approaches in the field of international relations—where it is simply called “realism”—around World War II (1939–1945), when Reinhold Niebuhr, E. H. Carr, Hans Morgenthau, and John Herz combined the logic of Machiavelli and Hobbes with the lessons of European statecraft in order to explain why international law and the collective security arrangement of the League of Nations had failed to prevent Japanese and German aggression, and to advise American leaders on dealing with the newly threatening Soviet Union. They argued that nothing but countervailing power can check an expansionist state, because the foreign realm lacks both the central authority and sense of community that hold domestic societies together. At root, the liberal effort to subordinate politics to the rule of reason—by enlightening people about their harmony of interests and the absolute respect owed to persons—must founder on the dark side of human nature. A realistic foreign policy consists of the firm and prudent use of power in pursuit of the national interest, which is primarily to provide security. Power consists most readily of military capabilities, followed by industrial capacity, natural resources, quality of leadership, and the size and morale of the population.
Whereas the first generation of realists in international relations relied on philosophical insight and historical experience to address particular foreign policy problems—an approach now called “classical realism”—the second generation embraced the methods of social science to explain state behavior in general. In the 1980s, this effort led to the ascendancy of Kenneth Waltz’s “neorealism,” which ignores the particular characteristics of states (e.g., their ideologies, economic systems, ties of friendship, and the personalities of leaders) in order to explain their behavior solely from the constraint exercised by the “anarchic structure.” This structure consists of the absence of central authority among states, and of the distribution of capabilities (i.e., power) across them. Neorealism predicts that states balance each other’s power either by their own efforts or in alliance with others, and that balances of power form recurrently in the international system.

Since the mid-1990s, the (intentional) inability of neorealism to account for variations in the behavior of states caused by their characteristics has prompted the rise of “neoclassical realism.” Its proponents insert the particular characteristics of a state—especially its perception of other states and its incentives arising from domestic politics—as a secondary cause, placing it between its structural position in the distribution of capabilities (the primary cause) and its foreign policy (the effect). It is hoped that this approach will yield a synthesis between the empirical richness of the case-study method and the analytical rigor of Waltz’s structuralism.

REALIST THEORY

Theoretical schools and trends represent more than abstract, free-floating ideas. They are socially moored, and need to be seen in relation to other intellectual and social trends. “Realism” has been present in philosophical thought at least since Aristotle, but the return of realism in recent years can be best understood as a reaction against the dominance of “postmodernism” in the academy, especially in the humanities and humanistic social sciences. What we have now come to call postmodernism (even when some of its adherents disavow the label) is a theoretical position that relies on a definable epistemic stance—what the philosopher Bernard Williams has called the stance of the “denier.” At the most general level, what is being denied is the value of such intellectual (and social) ideals as truth and objectivity.

The current version of realism in literary and cultural disciplines emerged as a response to postmodernism as an epistemological position. Drawing on sources in realist philosophy of science (e.g., the work of Putnam and Boyd; see Antony [1993] for a good exposition), and in solidarity with the progressive goals of postmodernist
thinkers, recent versions of realist theory, identified as "critical realism" or "postpositivist realism," attempt to go beyond both idealism and positivism without relying on the relativist and skeptical stance that characterizes postmodernist thought of various stripes (see Steinmetz 1998 on "critical realism," inspired by Bhaskar's work; on postpositivist realism, see Boyd 1988; Livingston 1988; S. Mohanty 1997, 2001, 2004; Moya and Hames-García 2000). In the social sciences, where postmodernism has had at best marginal influence, some critics of positivism invoke postmodernist theses about the social and discursive construction of social phenomena to move beyond narrow empiricism, but other theorists of social science, suspicious of postmodernism, are more robustly realist (see Calhoun 1995; Gilbert 2001). (Postmodernists and contemporary antipositivist realists share a commitment to one version or another of the social construction idea, but much depends on how that idea is specified and developed.)

Key postmodernist figures such as Jacques Derrida saw themselves as deconstructing the idealist substructure of "Western thought," the idealism that sometimes permeates even some self-avowed materialist approaches. Contemporary realists share the anti-idealist perspective of deconstruction and other strands of postmodernism but also develop a nonpositivist account of the very concepts postmodernists wanted to deny—concepts such as truth and objectivity most centrally, but also reference (Boyd 1988; S. Mohanty 2004), causation (Miller 1987; also see Somers 1998, a sociologist who draws on an alternative tradition of realism), identity, and experience (Alcoff 2000; S. Mohanty 1993; Moya and Hames-García 2000; Siebers 2004).

A serious debate between the postmodernist position and the contemporary realist one has barely begun, and narrowly partisan rhetoric, mistaking intellectual disagreement for political hostility, has prevented a genuine engagement. But the implications of the questions that are being scrutinized are large—and these questions could, for the first time in recent years, gather practitioners of the humanities and the social sciences together on common intellectual ground.

BEYOND POSITIVISM

Often, key theoretical slogans become more useful when their underlying claims are questioned and clarified. The postmodernist movement relies, for instance, on a critique of illegitimate and overly general historical accounts—what Jean-Francois Lyotard (1984) and many others following his lead called "grand narratives." On one level the rejection of grand narratives is a rejection of ethnocentric (Hegelian) accounts of entire cultures and civilizations. But on another level the critique extends more generally to all explanations—historical or social (see Spivak 1990 for one typical example). The danger with this approach is that it is too extreme, conflating as it does all kinds of idealization, legitimate and illegitimate. After all, all explanation (in the natural and the social sciences) requires idealization, the tracing of a perspicuous pattern through the vast mass of available data, and an indiscriminate skepticism toward all grand narratives and all explanations prevents us from distinguishing good, productive use of idealization from overly general and distorting ideal accounts.

A more useful critical approach would examine the ways in which both Hegelian idealizations of history and positivist methodologies, despite their differences, demand (as Richard Miller [1987] puts it about the latter) a debilitating "worship of generality." As Miller argues, the positivist "covering law" model of explanation relies on an overly abstract understanding of phenomena, given its primary commitment to "subsumption under general laws," scientific or historical. Realist philosophers of science such as Miller thus typically emphasize an approach that is more hermeneutical, reflexive, and dialectical.

The crucial antipositivist point made by realist philosophers of science and social science is this: Background or auxiliary theories, which are ineliminable, have epistemic significance; there are no theory-independent "methods" and there is no unmediated knowledge. This is a hermeneutical point on which they agree with such forebears of postmodernism as Martin Heidegger, who urged that we acknowledge the theoretical "forestuctures" of understanding. Realists such as Hilary Putnam and Richard Boyd would differ sharply from Heidegger's postmodernist descendants, however, by insisting that a nonpositivist objective knowledge is possible and that it is gained by taking the epistemic import of our background theories seriously. Putnam's antipositivist insights lead him and others not toward relativism or skepticism but to a sophisticated notion of objectivity as theory dependent and situated. On this view, objectivity is not neutrality; rather, it is the product of active engagement with the content and implications of our theoretical and ideological presuppositions. For Putnam and others, the postmodernist denial of objectivity rests, ironically, on an essentially positivist framework: The postmodernist thinks that the only possible form of objectivity is a positivist one, based on the idea of a completely atheoretical and aperspectival knower. And when the postmodernist (rightly) sees that such a knower is a dangerous fiction, a false myth, he or she (wrongly) concludes that objectivity as such is impossible to achieve. That conclusion follows only if one agrees with the postmodernist that the positivist conception of objectivity is the only candidate available. The nonpositivist account of theory-mediated (or theory-dependent) objectivity is an attempt to sketch an
alternative notion of objective knowledge that is dialectical, hermeneutical, and situated.

SCIENTIFIC KNOWLEDGE AND MORAL KNOWLEDGE
Richard Boyd (1988) makes the important argument that after recent developments in realist philosophy it is possible to see how the justification of moral claims is not altogether different from justification procedures in natural science. Both rely on a holistic process of achieving “reflective equilibrium” (Rawls’s phrase) among our various beliefs, theories, and rational conjectures. The sharp positivist distinction between the “hard” sciences and the softer areas of human knowledge is untenable on this view. Boyd proposes a materialist account of the human good as based on our best scientific understanding of human nature—our deepest needs and capacities, for instance—and on our best conjectures about how these needs can be met and these capacities realized. Realist thinkers argue that even the most “objective” moral—and aesthetic—theory be seen as corrigible, since it is the product of social inquiry. Even when such inquiry is based in everyday practice, it is rational—in the broadest sense of the word—and purposive, and hence not all that different from inquiry in the natural sciences (Babbitt 1996; Boyd 1988; Gilbert 2001; S. Mohanty 1997, 2001; Railton 2003).

REALIBATING IDENTITY AND EXPERIENCE
In literary and cultural theory, where postmodernist ideas have been immensely popular, realist theorists have outlined a series of proposals about such key concepts as experience and identity (and, more recently, values). Extending the nonpositivist view of moral objectivity to these social-theoretical domains, realists have argued since the mid-1990s against a purely constructivist view of experience and identity, showing how both can be not only “constructed” but also “real” (see Alcoff 2000, 2006; S. Mohanty 1993; Moya 2002; Moya and Hames-García 2000; Siebers 2004; Willkerson 2000). The key thesis here is that claims about our subjective experiences and social identities are mediated by ideology and social context, and by theoretical presuppositions, but are nonetheless evaluable claims. They are explanations, and can be evaluated by comparing them with other relevant and competing explanations—since they refer not to mysterious inner essences but “outward,” to key features of the social world and to the individual’s location in that world. This theoretical proposal counters the postmodernist argument that experiences and identities are purely constructed and hence epistemically unreliable (Culler 1982; Scott 1991).

Realists about identity argue, moreover, that the future of progressive social struggles depends on greater clarity about the ways in which identity claims are justified, clarity about where and why such claims are valid, and where and why they are specious. Realists propose that we take the epistemic content of experiences and identities of minoritized groups seriously, since they contain alternative (buried or explicit) accounts of the world we all share. The development of objective knowledge about society grows out of an engagement with such alternative perspectives (see the ongoing work of the Future of Minority Studies Project).

One important consequence of this rehabilitation of identity is we can see how the best kind of moral universalism (the kind that underwrites our conceptions of human rights, for instance) is compatible with those particularist moral claims that require us to take minority identities seriously. Instead of railing against all aspects of Enlightenment thought, realists suggest how the best strands of Enlightenment universalism can accommodate—and indeed complement—the identity-based struggles of minoritized groups (e.g., women, racialized populations, gays and lesbians, the disabled) in a modern, diverse society (S. Mohanty 1997; C. Mohanty 2003; Teuton 2006).

REALITY

In everyday usage, reality refers to the universe that exists independent of our thoughts. Dreams or delusions, which we experience when we are asleep or are otherwise not in full possession of our senses, are examples of the nonreal.

In philosophy, this commonsense view is known as realism. The opposing view in which only our thoughts are real is called idealism. An intermediate view is dualism, in which reality is composed of both the concrete objects of experience, which we call matter, and some other non-material element usually associated with mind and perhaps some external supernatural substance called spirit. While dualism is a common belief within most of the world’s religions, it is nonparsimonious in the sense that no evidence requires the complication of dual realities.

Spirit can be incorporated into either realism or idealism, although it is explicitly excluded in a form of realism called materialism. In the materialist view, matter and perhaps space and time are all that exist.

Associated with many thinkers since ancient times in both the East and the West, idealism asserts that our only knowledge of the outside world comes from perceptions, which are developed in the mind. So, it is reasoned but not proved that these are the only entities that can be real. The implication of idealism is that our thoughts are somehow more perfect, more truthful than the raw data that

Satya P. Mohanty
impinges our senses. Furthermore, perceptions that may be formed independent of the senses are equally real. Plato (c. 427–347 BCE) told the allegory of the cave, in which the cave’s inhabitants are constrained to view only shadows on the wall and cannot observe the sources of the shadows. He introduced the notion that reality is composed of perfect Forms such as the Form of the Good, which some interpret as Plato’s notion of God. In an example of Plato’s view, the planets travel in perfect circles around Earth, and their observed zigzag motion across the sky is a distortion, much as the images of our bodies are distorted when viewed in a funhouse mirror.

In modern times, many mathematicians and theoretical physicists have adopted an updated Platonic view of reality. Mathematical truths seem to exist independent of individual opinions and cultures. Some are not only unproved but also provably unprovable, yet they are known by other means to be correct (Gödel’s theorem). Furthermore, mathematical models in the physical sciences have the remarkable ability to predict future observations with exquisite precision. Surely, the argument goes, mathematics and mathematical physics must carry some aspect of reality. Yet they are still inventions of the human mind. Carried to its extreme, idealism implies that we should be able to make our own reality simply by thinking about it. Clearly this is not the case, despite the claims of some New Age gurus. Try as they might, none have been able to think themselves younger.

Each of us has an intuitive feeling that the concrete objects we confront during our waking experience constitute some aspect of reality. Samuel Johnson (1709–1784) expressed this common view when he heard of the idealistic philosophy espoused by Bishop George Berkeley (1685–1753). As described in James Boswell’s Life of Johnson:

We stood talking for some time together of Bishop Berkeley’s ingenious sophistry to prove the nonexistence of matter, and that every thing in the universe is merely ideal. I observed, that though we are satisfied his doctrine is not true, it is impossible to refute it. I shall never forget the alacrity with which Johnson answered, striking his foot with mighty force against a large stone, till he rebounded from it, “I refute it thus.” ([1791] 1934, Vol. I, p. 471)

When we kick an object and it kicks back, we are pretty certain that we have interacted with some aspect of a world outside our heads (and feet). In simple terms, this describes the processes of everyday observations as well as the most sophisticated scientific experiments. According to physics, when we look at an object with our naked eyes, particles of light called photons bounce off the object into our eyes. This process generates electrical signals that are analyzed by our brains. Essentially the same process takes place with scientific observations, where various particles besides photons and instruments more sensitive than the eye are used.

From the available data, scientists form mathematical models, or theories, to describe their observations and predict future observations. In the twentieth century, physicists developed the remarkably successful theories of relativity and quantum mechanics, leading to the standard model of particles and forces that accurately describes the nature of matter as we observe it. An equally successful standard model of cosmology has resulted from the application of the above theories to astronomical observations of increasing precision. With these theories, we can now describe the basic physics and cosmology of our universe from one trillionth of a second after it came into existence until the present. Surely the quarks and quasars of these models constitute some element of reality.

More than two thousand years ago, the Greek philosophers Leucippus (480–420 BCE) and Democritus (460–370 BCE) proposed that reality is composed of atoms and the void, where atoms were defined as particles that could not be divided further and the void was the empty space between atoms. This became the working model of Newtonian physics (Sir Isaac Newton, 1642–1727), although it seemed necessary to also include some kind of continuous, smooth background of fields to account for gravity and electromagnetism. In the nineteenth century, atoms came to be associated with the chemical elements, and that term is still used in that context. However, we have now cut the elements into smaller pieces in nuclear reactions.

In the twentieth century, it was found that theoretical quantum fields exist in one-to-one correspondence with particles, the so-called quanta of the fields. The quantum of an electromagnetic field is the particle of light, called the photon. The fields associated with forces that appear at the nuclear level have quanta called weak bosons and gluons. While a quantum theory of gravity has not yet been developed, it is speculated that the gravitational field will be associated with a quantum particle called the graviton.

Thus it remains possible, though not provable, that ultimate reality is composed of only atoms and the void, where the atoms are localized bits of matter, whatever the ultimate uncuttable objects may turn out to be. Einstein’s theory of general relativity, which led him and others to attribute a reality to space and time, suggests a connection between geometry and matter. The currently fashionable string theory supports that connection.

RECALL

Recall is an electoral procedure that allows citizens to vote on whether or not a public official should be removed from office. It is distinct from an impeachment, which involves a formal trial. A recall is simply a special election open to all voters in the area represented by the official in question. Similar types of procedures date back to ancient Athens, where politicians could be banished from the city by a vote of the citizens. The idea of citizens taking the initiative to remove public officials exists in many but by no means all local, state, and national jurisdictions. Depending on the political unit, the recall may apply to administrators, executives, judges, or legislators. Moreover, the grounds for recall, such as incompetence, malfeasance, neglect, and so on, may vary from jurisdiction to jurisdiction. In many cases no rationale is even necessary.

All recall procedures are typically initiated by a petition. The required number of signatories may be a percentage of citizens in the political unit or of voters in a preceding election. If the appropriate number of signatories is secured, then the official is recalled and an election is scheduled. There are at least four types of recall elections. In one type, a special election requires that the incumbent run in an election against all other contenders, with the winner assuming office. In another, a simultaneous recall and replacement election decides the fate of the incumbent separately but simultaneously with the choice of a successor. Voters cast ballots on the worthiness of the incumbent and the preferred replacement candidate. If the incumbent loses the recall, then the winner of the replacement election takes office. If the incumbent wins, then the outcome of the replacement election is moot. In a third type, a sequential recall and replacement election first decides the fate of the incumbent. Given that the incumbent is successfully recalled, then a replacement election is scheduled at a later date, with the vacant office filled by the winner. Finally, in the fourth type, a sequential recall and appointment procedure begins with a recall election. If the incumbent is voted out of office, then he or she is replaced by an appointee selected according to some constitutional provision.

In the early twenty-first century eighteen U.S. states allowed for the recall of public officials on the state level, and thirty-six states permitted the recall in local jurisdictions. The best-known contemporary example of this procedure is the 2003 recall of California governor Gray Davis. The governor was recalled in large part because of the state’s economic downturn and large budget deficit. In a contentious race, Davis lost the recall election and the Hollywood actor Arnold Schwarzenegger won the simultaneous replacement election. The event attracted much public attention because of Schwarzenegger’s celebrity, but it was also notable because state recall elections are rare and there had only been one other successful recall of a governor. In contrast, recalls at the local levels of government are used much more often.

Because the recall gives citizens the power to remove public officials before their terms expire, it serves the aims of direct democracy within a representative political system. It is consistent with an understanding of representatives as delegates for their constituents, as opposed to trustees. Proponents of the recall procedure contend that it advances democracy by increasing the accountability of public officials, giving them a reason to remain responsive to the general public. It also offers citizens the opportunity to more quickly remove incompetent, irresponsible, or unethical officials from office, instead of waiting for the end of their terms.

Opponents of recall procedures cite at least two basic problems. First, the recall is contrary to the principles of republican government because it undermines the independence of public officials. It encourages public officials to cater to the desires of citizens at the expense of the community, and it gives them an incentive to promote the satisfaction of short-term interests over long-term benefits. Second, recall elections are disruptive and costly. Recalled officials usually devote time to winning their elections so they can remain in office. More time spent campaigning means less time spent on serving the public. The recall is also expensive because it requires the government to conduct unscheduled elections.

When used judiciously, the recall can be an important tool for citizens to protect the integrity of their political systems. However, it can also be a destructive weapon...
when abused by an impetuous constituency or an opportunistic demagogue. Consequently, whether or not the recall is a good idea may depend on one’s confidence, or lack thereof, in the intelligence and savvy of the electorate.

RECESSION
A recession is the declining phase of a business cycle, when seasonally adjusted output falls significantly and unemployment increases, though by no means in every industry. A recession should not be confused with periods of low output and high unemployment. Early in a recession output, though falling, is still above its trend value. Similarly, shortly after the recession ends, output is still below its pre-recession level. Recessions should not be confused with depressions. While economic historians sometimes use this term to refer to conditions in the early 1890s, most American economists use it only in connection with the Great Depression, which started in August 1929 and encompassed one catastrophic recession until March 1933. This was followed by a recovery that was succeeded by another sharp recession from May 1937 to June 1938.

DETERMINING THE TIMING OF RECESSIONS
There are three major ways of determining when a recession has occurred. A popular one is two or more successive quarters of declining GDP (gross domestic product). This is simplistic. Suppose quarterly GDP grows at the following rates: –2.0 percent, 0.1 percent, –2.5 percent. Under this definition that would not be a recession. Moreover, since official GDP figures are issued only quarterly in the United States, it cannot provide the months of turning points, without relying on unofficial estimates. And looking only at a single variable, GDP, is risky because the U.S. Department of Commerce revises, sometimes substantially, its initial GDP estimates.

Economists therefore use more complex procedures. By far the most widely accepted is that of the National Bureau of Economic Research (NBER), a private research organization. As it explained in an October 21, 2003, press release titled “The NBER’s Business-Cycle Dating Procedure” it defines a recession as “a significant decline in economic activity spread across the economy, lasting more than a few months, normally visible in real GDP, real income, employment, industrial production, and wholesale-retail sales.” It determines when a recession started or ended by looking primarily at four statistical series, the most important of which is quarterly real GDP, supplemented by data that allow it to gauge monthly GDP. The other series it uses are real personal income minus transfer payments, employment, industrial production, and real wholesale and retail sales. Primarily because the initially issued data are subject to substantial revisions, it identifies the cyclical peaks and troughs only with substantial lags; for example it did not identify the November 2001 trough until July 2002. The NBER has also identified peaks and troughs back to 1857. To do so it had to rely on a large number of less comprehensive series, and on contemporaneous descriptions of business conditions. The table shows the NBER’s turning points.

Average, all 32 cycles: 37

Table 1
Although widely used, the NBER’s estimation of turning points has been criticized for being subjective or based on arbitrary rules. Take for example the following hypothetical growth rates \(-0.1, 0.1, -2.0, -1.8, -0.9\). Did the recession start with the 0.1 percent decline, or only with the 2.0 decline? Thus, Christina Romer estimated alternative turning points in her 1999 article “Changes in Business Cycles: Evidence and Explanations.” The largest discrepancy between the NBER and Romer’s estimates, five months, occurred in the 1982 trough. Another problem is the NBER’s delay in announcing turning points. Hence some economists developed methods that, using the growth rate of GDP in successive quarters, allow them to quickly determine in an objective way the likelihood that the NBER will subsequently declare that a turning point has occurred.

Following the NBER’s lead turning point chronologies have also been developed for other countries. There is some tendency for recessions to be synchronized in various countries since a recession in one country lowers its demand for the products of other countries, thus “exporting” part of its recession.

CHANGES IN THE SEVERITY OF RECESSIONS

There is much debate about whether U.S. recessions have been milder in the post–World War II era. What is clear is that recessions have become substantially shorter since 1983–1984, a phenomenon called “the great moderation.” The reasons for this are controversial. One hypothesis is that computerization has reduced inventory investment. That matters because about half of business-cycle fluctuations consist of fluctuating in inventories. However, the timing does not fit: Computerization has been a steady process, while the great moderation started abruptly. Another hypothesis points to other institutional changes: the larger role of government with its automatic stabilizers; the greater availability of consumer credit, which allows the unemployed to maintain consumption; and the shift from manufacturing to the more stable service sector. But these changes are not large enough to explain the great moderation. A third hypothesis points to the greatly increased efficiency of monetary policy. Finally, some economists attribute the moderation to good luck; that is, to the shocks to the economy being smaller since 1983. Several of these explanations may well be part of the story. In any case, unlike the fluctuations that the NBER measures, fluctuations in the unemployment rate have not become shorter. This is possible because the peaks and troughs in unemployment lag those of GDP.

Given that recent U.S. recessions have been moderate, how damaging are they? Some economists argue that relative to changes in the trend rate of growth they are unimportant. Imagine that the trend rate of growth falls from 3 percent to 2.75 percent. After thirty years income has grown by only 86 percent, instead of by 126 percent as it would have at the 3 percent growth rate, a 40 percent difference. Compare that to a recession that lowers GDP by 5 percent for a year. However, happiness studies have shown that above a certain threshold long-run per capita income has little effect on happiness, while temporary unemployment has a substantial effect. Moreover, recessions could reduce the trend rate of growth.

WHAT CAUSES RECESSIONS?

Explaining why initial declines in income are followed by subsequent declines is relatively easy. As their incomes fall consumers spend less, and falling sales also lower the incentive to invest. Moreover, if prices fall (or rise less than expected) the real interest rate exceeds the rate borrowers expected, and that may drive them into bankruptcy; a more salient danger in the nineteenth century when prices declined much more in recessions than they do now.

There is much less consensus on what causes the initial downturn. One should distinguish two types of explanations. The first considers recessions as endogenous (related to) to capitalism, with expansions generating forces that terminate them. The other considers recessions to be due to exogenous, or outside, shocks. An old-fashioned example of the former is underconsumption theory. A more modern version is that expansions generate overconfidence that leads to excessive borrowing, risky lending, and lax financial practices that make firms vulnerable to failure.

Modern theories stress exogenous shocks. Monetarist theory, which for major U.S. recessions has much empirical support, focuses on declines in the growth rate of money due mainly to bank failures (until 1934) and since 1921 to inept monetary policy. It faces the problem that the growth rate of money may be endogenous rather than causal. Another theory argues that recessions are due to negative shocks to productivity that lower equilibrium real wage, which workers, who do not know this, refuse to accept. Still another theory claims that the government adopts expansive policies prior to elections, and subsequently offsets them with restrictive policies.

More than one theory may be correct, because recessions differ. The 1914 recession was not preceded by a monetary shock, the 1921 recession was. The 1945 recession was due to end of wartime pressures for high output, while the 1973–1975 recession followed a doubling of oil prices to which the U.S. Federal Reserve Board initially responded with a restrictive policy, and the 1981 recession probably resulted from a major shift in monetary policy. The 1929 stock market crash may perhaps have played a
significant role in the severity of the 1929–1933 recession, while subsequent crashes did much less damage.

**RECIROCITY**

Reciprocity is mutual exchange. It is the back-and-forth movement of goods and services between people. Reciprocity is the defining characteristic of nearly every nonmarket exchange system, and it shapes formal market economics as well. Dynamic social and political aspects of mutual exchange significantly influence the production, distribution, and consumption of goods and services in all societies. Nuances in reciprocity also influence how various items and labor are imbued with culturally specific values.

Marshall Sahlins (1972), drawing on the work of Bronislaw Malinowski (1922) and Marcel Mauss (1925), pinpoints three overarching categories of reciprocal exchange among different past and present peoples: (1) generalized reciprocity, (2) balanced reciprocity, and (3) negative reciprocity. These distinct forms of mutual exchange often correspond with differing degrees of closeness in society. Whereas intensely social groups employ generalized reciprocity, moderately engaged communities practice balanced reciprocity, and distant networks of individuals commonly use negative reciprocity. Within a given culture, the different kinds of reciprocal exchange are not exclusive; multiple forms can coexist and be used for interaction with various groups.

Generalized reciprocity is driven by generosity and magnanimity. The exchange consists of pure something-for-nothing gifts. However, since the giver enjoys giving and gains satisfaction from the apparently one-sided transaction, the exchange is, in fact, reciprocal. Although givers engaging in generalized reciprocity may seem disinterested because they do not actively seek compensation for their altruistic actions, they are nonetheless rewarded with contentment for their good deeds. Westerners often only engage in generalized reciprocity when dealing with close family members and friends, but many non-Western societies employ generalized reciprocity on a much wider scale. Successful generalized reciprocity relies overwhelmingly on trust and interpersonal bonds.

Balanced reciprocity consists of giving that is later required and balanced by return offerings. The original giver must trust the recipient enough to know that the gift will ultimately be fairly and adequately required. Since there is always a danger that the initial gift will not be properly reciprocated, these offerings are often made public. The presence of an audience helps to ensure that gifts are properly repaid in two respects. First, they serve as a public record for exactly what was offered and accepted. Second, the local community can punish those who accept gifts without reciprocating by spreading word of the exchange transgression, thus socially humiliating ungracious recipients and discouraging others from making future gifts to them.

The timing of balanced reciprocity is essential to the success of this informal exchange system. Jacques Derrida (1992) asserts that the only thing the gift truly offers is time—“time to forget, time to return, time for delayed reciprocation that is no longer a return” (Schrift 1997, p. 10). Since an immediate countergift diminishes the necessary display of trust, the initial offering creates a temporal buffer. When discussing the time that a gift offers, Derrida identified a meaningful cross-cultural linguistic similarity between the term present as (1) a description of time and (2) a reference to an offering. All in one, the word present captures the duality of Derrida’s argument. A present—a material gift—provides the recipient with the present, the here and now. The offering requires future reciprocation yet frees the recipient from doing anything in the present; it provides the recipient with time. In a single word, the present presents the present (Mallios 2005).

Mauss notes an important link between perceptions of generalized and balanced reciprocity. He poetically writes, “Society always pays itself in the counterfeit coin of its dream” (Bourdieu 1997, p. 231). Mauss’s metaphor captures two distinct aspects of the gift. “Society paying itself” is a reference to obligatory reciprocation, the mandatory return offerings made by individuals engaging in balanced reciprocity. Yet, the exchange is made “in the
counterfeit coin of its dream,” an offering that maintains the superficial form of pure something-for-nothing generosity. It appears to be a selfless act of altruism. Although these transactions are indeed mandatory, they are physically indistinguishable from blissful magnanimity. The dream is generosity; the hidden reality is the obligation to give (Mallios 2005).

Negative reciprocity is trade. It is the simultaneous and immediate exchange of one good or service for another. Trade can be characterized by antagonistic haggling or complete anonymity. The transaction is in no way dependent on trust or the closeness of the individuals involved in the exchange. The only relationship of significance is the equation of exchange values between the goods or services being traded.

Chris Gregory (1982) summarizes the differences between balanced reciprocity and negative reciprocity. Calling the former a gift-exchange system and the latter a commodity-exchange system, Gregory explains that, “Commodities are alienable objects transacted by aliens; gifts are inalienable objects transacted by non-aliens” (1982, p. 42). One is a sale between strangers; the other is a loan between friends. There is also an important exchange-form distinction that adds to Gregory’s dichotomy: commodities are alienable objects *traded*—something for something—by aliens; gifts are inalienable objects given—something for nothing—by non-aliens (Mallios 2006). Although the initial gift in balanced reciprocity mandates a return gift and is ultimately an exchange of something for something, it nevertheless takes the meaningful form of something for nothing. Gregory presents these two models as opposites, with the giving of inalienable goods between permanently allied and perpetually interdependent transactors on one side and the trading of alienable goods between momentarily allied and perpetually independent transactors on the other.

Distinct differences exist between the world’s many economic systems that are based primarily on balanced reciprocity. Anthropologists often use the terms *limited* and *unlimited* exchange to describe an important difference within these economic systems. Limited exchange confines the interaction between a set of partners. It is symmetrically dyadic, meaning that one person gives an item to someone else and that recipient makes a return offering back to the original benefactor. The most common form of reciprocal interaction, limited exchange includes only two people—that is its inherent limitation—and only two sets of offerings. Unlimited exchange, to the contrary, is open-ended. Different people pass gifts on asymmetrically in a series of exchanges. In this case, a person gives a present to another individual, who then regales a third person. Unlimited gift exchange spirals outward to include multiple parties, one of whom will ultimately make an offering to the original gift giver. This final present completes the circular exchange system. Ideally, blood donation in the United States follows a process of unlimited gift exchange. People who give blood pass their offering onto anonymous others, who then feel obliged by these magnanimous gifts to repeat the action at some point later in time. In the long run, donors participating in a successful system of unlimited balanced reciprocity are able to depend on the available blood donations of equally anonymous others should they find themselves or their loved ones deficient. The driving force behind seemingly random acts of kindness, unlimited reciprocity establishes a favorable gift karma that its participants expect to produce far-reaching benefits for all.

A similar distinction concerns *even* and *incremental* exchange. Even gift giving results when an offering completely cancels out a previous debt. A present that both eliminates debt and creates a new obligation contributes to incremental gift giving. Repeated incremental gifts further connect exchange partners as they continue to seesaw back and forth in terms of debt owed and debt accrued. This type of gift exchange is more common than even gift giving for the simple fact that evenness is not a primary goal or concern in the gift economy. Social reciprocity hinges on creating and enhancing mutually beneficial relationships, not canceling them out.

Undermining reciprocity is more than a simple economic transgression. Mauss explains that, “To refuse to give, just as to refuse to accept is tantamount to declaring war; it is to reject the bond of alliance and commonality” (1925, p. 13). Failure to perpetuate reciprocal exchanges and relationships that draw individuals closer together, in fact, pushes intended exchange partners away from each other. This denial frequently leads to conflict. Claude Lévi-Strauss (1969) identified a link between exchange and hostility. He writes in specific reference to native Nambikwaras of western Brazil and in general of societies that engage in balanced reciprocity, “Exchanges are peacefully resolved wars, and wars are the result of unsuccessful transactions” (Lévi-Strauss 1969, p. 62).

One of the most pronounced examples of a reciprocity-based culture clash occurred in 1607 at Jamestown Island, the first permanent English settlement in the Americas. Historical records and analogous ethnographic accounts reveal how profit-minded English colonists and their emphasis on negative reciprocity collided with the Powhatan’s indigenous expectations of balanced reciprocity (Mallios 2006). The English failed to reciprocate the Paspahgehs—geographically the closest tribe in the Powhatan chieftdom to the new European outpost—on four separate occasions during the first weeks of colonization. Wowinchopunk, the local leader of the Paspahgehs, gave the settlers food, the land on which the colonists
would build James Fort, and other goods, but the English made no return offerings. The natives grew frustrated, at one point even attempting unsuccessfully to steal reciprocal items. A Paspahegh warrior took an iron hatchet from the English camp following the series of unrequited native offerings, but a colonist snatched it back in a confrontation that nearly erupted into violence. Immediately following English trade with indigenous social rivals and enemies of the Paspaheghs, Wowinchopunk and his followers spearheaded a multitribal attack on the colonists at James Fort. Overall, exchange transgressions by the English—they failures to give, accept, or reciprocate property—immediately preceded nearly every intercultural assault at Jamestown during the colony’s first five years.

RECIPIRICITY, NORM OF

Social norms refer to the rules and expectations about how people should behave in a group or culture, and pertain to generally accepted ways of thinking, feeling, and behaving that people agree on and endorse as right or proper. Various norms can be distinguished: among others, the norm of social responsibility, prescribing that people should help others who are dependent on them; the norm of social justice or fairness, which relates to the just distribution of resources; and the norm of social commitment, which concerns the shared view that people should honor their agreements and obligations.

American sociologist Alvin Gouldner (1960) was the first to propose the existence of a universal, generalized norm of reciprocity. He argued that almost all societies endorse some form of the reciprocity norm, and that only a few members were exempt from it—the very young, the sick, and the old. The norm regulates the exchanges of goods and services between people in ongoing group or individual relationships, dictating that people should help those who have helped them, that people should not injure those who have helped them, and that legitimate penalties may be imposed on those who fail to reciprocate. Reciprocity thus calls for positive reactions to favorable treatment and for negative reactions to unfavorable treatment. The things exchanged may be heteromorphic; that is, the goods or services may be concretely different but equal in value, as perceived by the exchange partners. Or the things may be homomorphic; that is, the goods or services may be roughly equivalent, or identical. Recent developments indicate support for Gouldner’s general statement concerning the universality of the norm (Cosmides and Tooby 1992; Ridley 1997; Sober and Wilson 1998; for primates, see De Waal, 1982, 1996).

The norm has important social functions in ongoing relationships. It increases social stability in social groups or systems, and it structures and maintains the social relationships. Additionally, reciprocity may function as a positive, facilitating starting mechanism for the development of stable and enduring social relations in newly formed relationships. If a future time perspective is imposed in the social exchange relationship, the norm hinders the pursuit of nonreciprocal, selfish, and/or exploitative moves on the part of the exchange partners, thereby fostering mutual cooperation between them. As such, the time variable increases stability in the social system through reciprocity (Axelrod 1984).

Reciprocity is an evolutionary factor that can favor, among others, altruism among kin (kin selection; Hamilton 1964), and nonkin (reciprocal altruism, Trivers 1971; Axelrod and Hamilton 1981). As such it is an important factor in the social exchanges of many species, including humans, influencing such diverse behavior as helping (Lorenz 1966), cooperation (Axelrod 1984), compliance with requests in economic exchanges (Cialdini 1993), dealing with conflict and associated health impairments in organizational settings (Buunk and Schaufeli...
Reciprocity, Norm of

1999), and bargaining and negotiations in conflicts in international settings (Lindskold 1978).

To indicate its relevance in social relationships, mechanisms have evolved to detect cheaters (that is, nonreciprocators, or exploiters; see Cosmides and Tooby 1992; Wright 1994). Furthermore, research on negative reciprocity has shown a strong relationship between the violation of the reciprocity norm by cheaters and norm-enforcing, punitive, aggressive actions, exemplifying the lex talionis, or the “eye-for-an-eye” tendency. This research involved computer simulations by Axelrod (1986: punitive meta-norm) and Boyd and Richerson (1992: moralistic strategies); research among primates by Brosnan and De Waal (2003: equity aversion); and neuropsychological studies among human subjects (e.g., De Quervain et al. 2004: altruistic punishment). The findings of all these studies generally revealed that (a) parallel to the norm of reciprocity in social exchange relationships, secondary, punitive norms have evolved that dictate the legitimate, aggressive enforcement of the former one in different species, and (b) that effective retaliation against transgressors or cheaters may be more satisfactory than ineffective retaliation.

A pervasive phenomenon in intergroup relations is in-group favoritism, or in-group bias. Individuals evaluate their own group (or in-group) and its members more favorably than an out-group and its members on relevant dimensions, or they allocate more of a valued resource (money) to in-group members than to out-group members. Many social-psychological theories, such as social identity theory (Tajfel and Turner 1986) and self-categorization theory (e.g., Hogg 1992), serve as the main explanations for this phenomenon. However, recent developments indicate that in-group reciprocity can also at least partially account for this pervasive intergroup behavior (Gaertner and Insco 2000; Rabbie and Lodewijkx 1994; Stroebe, Lodewijkx, and Spears 2005).

RECOGNITION

Recognition is a term that has been increasingly employed in the social sciences. In psychology, the term usually refers to identifying external objects or to other mental processes. In other disciplines within the social sciences, recognition has been used rather freely to denote an act of or motivation for acknowledgment of certain demands, goals, values, and identities. It is this latter social and political meaning of recognition that has increasingly become a matter of importance, moral concern, and focus of scholarship.

At the level of the individual, the importance of recognition can be observed when, for example, one person assaults another person due to what is perceived as a lack of respect or recognition. The "code of the streets" emphasizes recognition and "saving-face" as issues of the highest importance. At the collective level, people strive for recognition of group values, identities, and reparations for past wrongs. To recognize, in this sense, means to behave in a manner that satisfies expectations of respect and contributes to a sense of positive self-esteem in those who are recognized.

The psychological motivation for recognition is defined in social psychology as the pursuit, defense, and maintenance of positive self-esteem. In fact, recognition and self-esteem are often used interchangeably because positive self-esteem is intertwined with, and affected by, attitudes of others, such as the granting or withholding of social acknowledgement. Social psychologists assert that positive self-esteem contributes to optimal functioning, higher efficacy, development (self-enhancement), happiness, satisfaction with life, better performance, persistence at tasks, and reduced anxieties. In contrast, low self-esteem is strongly associated with mental disorders, malfunctioning, antisocial behavior, aggression, delinquency, and opposite traits and effects of positive self-esteem. Because recognition enhances positive self-esteem and the lack of recognition tends to produce low self-esteem, it is understandable that people are highly motivated to pursue recognition and may act aggressively if denied recognition.

The notion of recognition has also been examined in philosophy. Plato identified recognition with the rhymos, the enthusiastic part of the soul that seeks honor and pride. Thomas Hobbes argued that people are led by a natural human passion for fame and honor, which is a desire to be recognized by others. Many other political philosophers discuss recognition as esteem. G. W. F Hegel, however, was the first to discuss recognition in the context of the relationship between a master and a slave, and to suggest that equal recognition is the key for the development of human freedom over the course of history. Several political philosophers were influenced by Hegel's conception of recognition, such as Karl Marx, Alexandre Kojève (1902–1968), and Francis Fukuyama (1952–).

Later in the twentieth century, the notion of recognition was discussed in new contexts. John Rawls argued that to acknowledge the moral duty of fair play is to recognize others as human beings with equal aspirations and interests. According to Rawls, this recognition is a necessary element of just societies. Charles Taylor introduced the idea of recognition in the debate on multiculturalism and differential treatment of minority groups. In the opening of his treatise "The Politics of Recognition" (1992), Taylor argues that contemporary politics had become significantly shaped by needs and demands for recognition. Because identity and self-respect are affected by recognition or the lack thereof, and because nonrecognition or misrecognition can inflict real harm and serve as a form of oppression, Taylor argues that recognition is not only a matter of a moral obligation to others, it is a vital human need.

The transition from the normative to the descriptive aspect of recognition also characterizes Francis Fukuyama’s The End of History and the Last Man (1992). Following Hegel, Fukuyama argues that the pursuit of recognition is part and parcel of human nature. Fukuyama discusses the moral aspects of recognition and the necessary acceptance of equal recognition as the foundation for liberal democracy, but he continues to suggest that recognition is also the causal engine of democratization. Nondemocratic regimes tend to inflict a sense of low self-esteem in the population, and hence the oppressed become motivated to regain a sense of recognition and human dignity. They can achieve this only through the establishment of a democratic order that entails equal recognition to all citizens.

Given the importance of recognition to self-esteem, and the growing awareness that demands for recognition are often voiced in politics, the pursuit of recognition may become the new frontier of research as an explanatory factor to various social and political phenomena. An array of social change phenomena seems to be associated with the pursuit of recognition, at least as members of social change movements express their ultimate goals. This has been the case for slaves and other oppressed groups, feminist groups, and minority groups. Democratization also
appears to be affected by struggles for recognition, as demands for political and civil rights are often demands for recognition. Struggles for recognition are usually expressed as struggles for human dignity and against humiliation, and for restoration of self-esteem and similar concepts that are associated with self-respect and self-esteem. As such, the pursuit of recognition appears to lie at the heart of political life. Recognition, thus, has become not only an important normative concept, but also an overarching explanatory concept.

RECONCILIATION

Reconciliation, the overcoming of differences, the healing of broken relations, is initially a religious concept addressed in the Hebrew Bible and especially in the New Testament. It has acquired wider meaning in the context of the wars and violence of the twentieth century.

In the Hebrew Bible, the term kafar (from the verb kaffar: covering over, atonement, propitiation, reconciliation) was used in the context of animal ritual sacrifice. Propitiation of God was the objective. Saint Paul, especially in 2 Corinthians 5:18–20 and in Romans 5:10, raises this concept to the level of a restoration to the favor of God for sinners who repent and put their trust in the expiatory death of Christ. But the term refers not only to such reconciliation with God but also to the task of reconciliation with other persons as a primary requirement for the followers of Christ. In Matthew 5:23–24: "If therefore you are presenting your offering at the altar, and there remember that your brother has something against you, leave your offering there before the altar, and go your way; first be reconciled to your brother, and then come and present your offering."

In the Gospels, as in much later discussion, reconciliation came to be paired with the concept of forgiveness, the forgiveness freely given by God and to be imitated by all. In this, the New Testament’s reconciliation with God and with others took on the full character of the Hebrew Bible’s shalom: completeness, soundness, welfare, peace. Yet in practice, the concept long tended to be confined to the private sphere, the individual's forgiveness by God, as in the Catholic practice of confession to a priest and the absolution of sins, now called the sacrament of reconciliation rather than, as in the past, of penance.

But the wars of the twentieth century and the many situations of transitional justice (the restoration of civil relations after periods of oppression) brought the wider social-political concept of reconciliation back into prominence in Christian thinking and made it the property of all the world. Thus, in South Africa, the effort to heal the society after the ills of apartheid gave rise to the Truth and Reconciliation Commission. Its grant of amnesty to offenders, on condition that they admit their guilt, was seen as far more satisfactory than the more vengeful process of the Nuremberg Trials after the collapse of Nazism. We can observe an outgrowth of this development in the growing interest in restorative justice, a legal concept that defines the objective of a justice system as the restoration of relations rather than simply the determination of guilt and the punishment of the offender—retributive justice.

Christian proponents of reconciliation, such as Archbishop Desmond Tutu of South Africa or the Croatian theologian Miroslav Volf, have consequently held prominence in this movement, although it has also been taken up as a managed and secular technical process conducted by professional mediators. Realization of the benefits that can be derived from this kind of process has brought about the rise of Track II diplomacy, the work of nongovernmental peace-building professionals who can often help the citizenry of conflicted societies reach reconciliation in ways that the official diplomatic representatives of governments cannot, or who can be the catalysts of solutions to conflict that governments could not generate themselves.

Distinguishing between the concepts of forgiveness and reconciliation has troubled many. We may see forgiveness as the personalized action of individuals and reconciliation as the effect of the healing of relations in the broader society.

Welcome as all this has been in its humanity and generosity, it carries its dangers. Most obvious is that a demand for instant forgiveness and reconciliation, and a
blaming of victims who cannot bring themselves simply to forget the evils done to them, can lead to the hasty covering up of severe trauma in a society, leaving the underlying ills unaddressed. Connected with this is the tendency, sometimes, of churches and religious actors, as well as those who most benefit from systems of exploitation, to treat reconciliation as an alternative to the liberation of victims of oppression, imposing a sense of guilt on them if they persist in their quest for justice rather than reconciling themselves to an unjust status quo. In an atmosphere in which reconciliation is seen as a virtuous action, superior (more religiously acceptable) to the pursuit of justice, this can take on the character of blackmail. And in this context the professionalization of the mediator’s task in managing conflict can easily become an unwelcome form of coercion.

Warning indications hang, therefore, over this valuable practice and concept of reconciliation. An understanding is required that unfair disparities of power between victims and controllers of society may not be tolerated. The third-party reconciler must realize that forgiveness is not an instant process, and that those who feel themselves victimized, often from both or all sides of a conflict, must have time to mourn, to lament the harm that has come to them. They must have an opportunity to learn, through what may be a difficult and time-consuming process, the common humanity of those who have hurt them. They and their victimizers need to unlearn the stereotypes by which they have perceived one another. And all the participants need to understand that it may not be possible to resolve all problems and contentions among them, but that the more promising course is a conflict transformation by which the relations among them are seen in a different light.

Setting the objective of reconciliation, however, rather than simply a cessation of violence or the stifling of protest, as in a military process of “pacification,” holds promise to bring about more humane relations among peoples, possibilities of addressing their inevitable differences of interest or aspiration nonviolently, and the healing of past traumas in ways that do not call for visiting retributive trauma on those who have harmed us. The development, as rather a new discipline, of peace studies has been a result of the renewed social and political interest in the concept of reconciliation.

RECONSTRUCTION ERA (U.S.)

The Reconstruction Era refers to the period following the Civil War from 1865 to 1877, during which the victorious North reorganized, or reconstructed, the Southern states that had formed the Confederacy. This reorganization was carried out under the requirements of the Military Reconstruction Act passed by the U.S. Congress on March 2, 1867, hence the term Reconstruction. But the attempt to reorganize the South’s political system in order to move the region in a new direction, away from the priorities and practices of the slavery regime, ran into difficulties. By the early 1870s, governments formed under the provisions of the Reconstruction Act were encountering such opposition and hostility from the former Confederates that they were unable to stay in power. After the contested presidential election of 1876, the federal government withdrew its political support and its troops from the South, bringing the Reconstruction experiment to an end.

THE VICTOR’S BURDEN, 1865

The Civil War was precipitated by the decision of the Southern states to secede from the Union in 1860–1861, but it was caused by the Southerners’ long-term fear that their valuable and profitable institution of slavery was endangered by a hostile majority in the North. This fear came to a head with the election of a Republican, Abraham Lincoln, to the presidency and his Northern party’s capture of Congress. As a result of the war, secession was defeated and slavery abolished. Alarmingly, however, the successful resolution of the long-term cause of the war (slavery) and of the short-term cause (secession) did not end the matter. Rather, it gave rise to new problems. First, what was to be the future status of the emancipated slaves? How free would they be and did freedom
involve equality of some kind? Would they obtain land, as several Union government actions during the war had hinted? Second, what was to be the future status of the rebels who had been defeated on the battlefield? Would they be allowed to return to the Union they had broken up four years earlier and, if so, under what terms? Terminating slavery and Southern independence had solved one set of problems, but emancipation and reunion immediately presented another, as massive and vexing as the first. Even more was at stake, however, because failure to handle emancipation and reunion satisfactorily would raise doubts about how much the Union's victory had ultimately achieved. The North had won the war, but it might lose the peace.

PRESIDENTIAL RECONSTRUCTION, 1865

After the war, the federal government was embroiled in a struggle over the terms for readmitting the South to the Union. Instead of collaborating, the president and Congress found themselves dangerously at odds over the appropriate course to pursue. The conflict centered on the fundamental issues of what policy would be adopted and which branch of government would prevail. But it was exacerbated by the personality of Andrew Johnson who had succeeded to the presidency when Lincoln was assassinated just a few days after the Confederacy's surrender on April 9, 1865. A stubborn and combative man, Johnson was a Southern Democrat who had stayed with the Union after his state had seceded in 1861 and who had practiced politics in Tennessee as the art of confrontation, rather than compromise.

Promulgated in May 1865, Johnson's plan for the South required that new governments be formed in each state, elected by voters who had sworn an oath of loyalty to the United States. But Johnson's conciliatory scheme soon encountered difficulties because even its minimal requirements were questioned and sometimes rejected by the Southern states, and the voters sent prominent Confederates to Congress, among them the former vice-president, Alexander H. Stephens. Simultaneously, reports of mistreatment and violence toward the freed slaves (the freedmen) were pouring into Washington and began appearing in the newspapers. Not surprisingly, the Republican majority in Congress rejected the South's congressmen-elect.

Rather than adapting to the emerging realities in the South and changing course, as Lincoln would almost certainly have done, Johnson stood his ground. He proceeded to thwart the efforts of the Republicans to formulate alternative proposals for the South, resorting to his veto power on every possible occasion. This extremely dangerous confrontation continued until 1868 when, after several attempts had been defeated by a veto-wielding president, Congress managed to enact and implement a reconstruction policy that readmitted the South to Congress and established a Republican-controlled government in each of the ex-Confederate states.

CONGRESSIONAL RECONSTRUCTION, 1866–1867

After taking the initiative in December 1865, Congress proposed three different approaches for dealing with the South. The first took the form of two measures, introduced in early 1866, to protect the freedmen who, although no longer slaves, were still vulnerable and in need of physical and legal protection. One measure extended the life of the Freedmen's Bureau, a wartime agency created to supervise the transition from slavery to freedom and provide relief for the destitute of both races in the war-torn South. The other was a civil rights bill that defined citizenship as a national, not state, matter, and therefore extended citizenship to 4.5 million African Americans, all but 500,000 of whom had been slaves. The statute also provided federal protection for the civil rights of all citizens, that is, equality before the law, ensuring equal access to the courts and prohibiting legal discrimination. Although the Civil Rights Act marked a major expansion of federal jurisdiction, it was still limited in scope because it did not ban private discrimination, and the federal government could only intervene when a state failed to provide formal legal protection. Nevertheless, to most Republicans' surprise, the president rejected both bills, accompanying his vetoes with hostile messages that pronounced them unconstitutional. Although the vetoes were soon overridden, Johnson clearly intended to oppose Congress. Furthermore, by vetoing the Republicans' proposals and declaring them unconstitutional, he was obviously provoking a fight.

Congress's second initiative was a set of terms for readmission in the form of a constitutional amendment to be submitted to the Southern legislatures elected in 1865 under Johnson's plan. The Fourteenth Amendment, as it became known after its ratification in 1868, consisted of three basic propositions. First, a federal guarantee of citizenship and civil rights, incorporating the provisions of the Civil Rights Act into the Constitution. Second, a reduced representation in Congress for the South if African Americans were denied the vote. And third, the disqualification of leading Confederates from holding office. The civil rights clause became the enduring protection feature, but it was the third clause—keeping former Confederates out of power—that made the proposal unacceptable to the South in 1866. Accordingly, the Southern legislatures rejected the amendment decisively,
following the president's earlier and predictable veto. In the congressional elections of 1866, Johnson's determination to defeat his former Republican allies and their proposed amendment had led him to create a party of his own called the National Union party, with the Northern Democrats as its primary source of support. But it had been defeated overwhelmingly, allowing the Republicans to increase their majority.

With the president still defiant and the South emboldened, the Republicans moved quickly to produce yet another plan before the Thirty-ninth Congress expired in March 1867. The outcome was a law, the Military Reconstruction Act, the terms of which would be mandatory, unlike an amendment that needed to be ratified by the states. As first introduced by Thaddeus Stevens of Pennsylvania, the leading radical Republican in the House, the bill was conceived as a program for keeping the South under federal military supervision, for several years perhaps, until loyalty returned and changes were under way democratizing the region's political system and modernizing its economy. The radical wing of the party saw the postwar moment as a critical opportunity to move the South in a new direction, but Republican moderates amended Stevens's bill so thoroughly that it became instead a formula for immediate readmission.

Under the terms of the law, the eleven Southern states were divided into five military districts, each of them under the command of a U.S. general. The troops stationed in each district were to supervise the creation and registration of a new electorate that was to include all adult male African Americans. Black suffrage was a radical innovation never even contemplated by other slave societies in the Americas, although none of them had been forced to end slavery after defeat in a massive civil war. The new electorate included just under a million African Americans. Black suffrage was a radical innovation never even contemplated by other slave societies in the Americas, although none of them had been forced to end slavery after defeat in a massive civil war. The new electorate included just under a million African Americans, but not the leading Confederates who were now disfranchised by the Act. These former Confederates were also barred from holding office under the Fourteenth Amendment, which the reconstructed states were required to ratify.

The Reconstruction Act became law—over Johnson's veto, of course. Immediately, the process of reconstructing the South began and it required that new governments be created and Congressmen elected. As a result, a Republican party was formed in the South and the Republicans proceeded to gain control of every Southern state and its Congressional delegation. This outcome was achieved, despite constant opposition from President Johnson who used his authority as chief executive and commander in chief to obstruct the implementation of the complicated political process laid down by the Reconstruction Act. Also presenting a problem was the South's political class whose members opposed, not only the idea of enfranchising their ex-slaves, but also the creation of a new political order from which they were to be excluded. As the South was being reconstructed, Johnson was impeached for his persistent obstruction, although the Senate failed to produce the two-thirds majority needed to convict and remove him from office. Meanwhile, the former Confederates, who were now out of office but actively organizing an opposition party, lived to fight another day.

**RECONSTRUCTION IN THE SOUTH, 1868–1877**

The newly created Republican party managed to win control of every Southern state between 1868 and 1870. The success of Reconstruction now depended on how well the party governed and how long it could stay in power. This task was enormously difficult, not only because the party was new to the region and most of its elected officials were inexperienced, but also because it was faced by a relentless foe determined to see it fail. In the eyes of the conservative opposition that consisted of former Confederate officeholders and most of the region's political class, the Republican-controlled state governments were unworthy of their support, and therefore they were deemed illegitimate. The federal government had created the party, and the state governments that the party controlled had been imposed upon the South. Moreover, the party's constituency and leadership were drawn from elements that were alien and unacceptable, namely, Northerners whom they called derisively carpetbaggers, Southern whites dismissed as scalawags and, of course, blacks, most of them ex-slaves.

Besides ridiculing and vilifying these Republican governments, the opposition employed every means possible for attacking, destabilizing, and ultimately overthrowing them, one by one, during the early 1870s. They resorted to electoral fraud and intimidation. They frustrated the operation of these state governments by withholding taxes. They broke up the Republican coalition by encouraging dissidence among the racial and sectional groups within it and then offering to give electoral support to any faction prepared to leave and run an independent campaign. And when the masked and secret Ku Klux Klan emerged in 1868, intimidating Republican supporters and assassinating some of the party's leaders, the conservatives did nothing to discourage this insurgency until the federal government intervened in 1871–1872. By 1872, many of the states with white majorities had slipped from Republican control, a result of favorable electoral conditions for the opposition, supplemented by pressure, fraud, and violence.

Although the Klan was subsequently dispersed, the violence soon assumed a different and more deadly form as
the paramilitary White Leagues appeared in Louisiana in 1873 and various other overtly violent organizations arose in the Deep South that was still under rather precarious Republican control. The Republicans’ opponents, who were at that time aligning with the Democrats and determined to regain control of their states, officially sanctioned these forces that styled themselves Rifle Clubs or Red Shirts. Accordingly, they unleashed virulent and violent race-based campaigns aimed at rousing white voters and discouraging blacks and carrying elections “peaceably if we can, forcibly if we must.” Faced by this onslaught, the last remaining Republican governments located in the heavily black states of Alabama, Mississippi, South Carolina, and Louisiana were overthrown between 1874 and 1876. A few months later, federal troops were withdrawn, allowing the Democrats to take over throughout the region.

Painfully aware at the outset that the opposition was going to be fierce, the Republican state governments were caught in a dilemma. They had to provide for and protect their supporters who were, for the most part, former slaves and less advantaged whites. Simultaneously, the governments they controlled had to govern the state as a whole, while defusing the criticism of the conservatives and fending off their attacks. Pulled in these two different directions and under constant attack, the party began to collapse. Nevertheless, the Republicans began well. In 1868, they drew up a new constitution for each state, as required by the Reconstruction Act. Liberal and democratic in thrust, these constitutions reduced privilege and increased political participation, and also provided government services previously lacking in most Southern states. They made adult male suffrage a constitutional right, lowered or removed age- and property-qualifications for holding office, and ensured that most offices were elective rather than appointive. Government assumed responsibility for creating and funding institutions to care for orphans, the insane, and the deaf and dumb, as well as for building penitentiaries and systems of public schools. Because government was to be more active than before, the powers of the executive branch were increased.

But the Republican framers of these constitutions proved unwilling to push much further. They did not provide for any redistribution of land to the landless, in particular the freed slaves who felt they deserved a portion of the land that had gained value from their unpaid labor (the possibility of making land available to the former slaves was all but eliminated by earlier developments at the national level, first, by Johnson’s executive proclamation of August 1865 allowing the rebels to regain their lands and, then by the Republican party’s general lack of enthusiasm for pursuing such a policy). The public schools were to be racially separate, a decision actually favored by black delegates because they feared losing the entire system if white parents refused to send their children to schools attended by blacks. And the constitutions usually removed the ban on former Confederates holding office, because the Republicans who wrote them favored equal rights, even though this liberality would allow the South’s political class to reenter politics.

Cautious and moderate rather than extreme, these new constitutions provided the framework for Republican rule. Although the party leaders hoped that this constitutional foundation would satisfy their supporters and reassure their opponents, they knew that successful programs were needed if the party was to consolidate its power and acquire legitimacy. To this end, the Republicans promoted three initiatives in particular: the creation of a viable school system, the protection of civil rights, and the development of the region’s railroad system. Of these three, the railroads were considered critical in the Republicans’ attempt to prove that they could govern efficiently and effectively. Accordingly, the Republican legislatures moved forcefully to encourage economic development by offering state aid to builders of railroads in the hope that they would create vital infrastructure and develop the localities that their roads penetrated and opened up. Had these ventures succeeded, the Republicans expected to gain considerable political capital. But, for a variety of reasons, they failed. The states were left holding the debt of these enterprises and, somewhat unfairly, the Republicans were accused of mismanagement and fiscal irresponsibility, but not the railroad companies that had actually failed to build the lines.

This serious setback was compounded by the party’s inability to raise the necessary revenue to fund the public schools adequately, a direct result of the taxpayers’ unwillingness to pay and of the precipitous decline in the value of the land on which the school tax was levied. Also disappointing was the party’s record on race relations. Despite legislation to end racial discrimination on transportation and in other public places, the patterns of segregation established under slavery remained the norm. Whites were unwilling to break with the past, and blacks themselves were hesitant to challenge these customs, believing it was safer and more constructive to develop their own institutions, a calculation similar to the one they had made earlier over mixed schooling. Nevertheless, most black and many white children attended school during and after Reconstruction, and a significant cadre of African Americans were trained as teachers. In addition, hundreds of African Americans held office under the Republicans. Two hundred sixty-seven were delegates to the constitutional conventions in 1868; nearly 800 served in the state legislatures during Reconstruction; and 18 held national office as members of Congress. Meanwhile, hundreds more served in lower-level positions, such as sheriff, county commissioner, justice of the peace, and even an occasional mayor. Although inexperienced, these
officials were usually literate and their visible presence in public life was evidence that race relations were improving, somewhat dramatically in fact.

Unfortunately, African Americans, and most of the white population who also stood to gain from the Republicans’ new initiatives, depended upon the Republican party’s ability to remain in power. But the Democrats relentlessly opposed the Republicans. They subverted and attacked the Republicans and were quick to exploit their mistakes and aggravate their difficulties. By the mid-1870s, less than a decade after the South had been politically reconstructed, the Republican party had lost control, either through its inability to hold its diverse coalition together or by losing elections because of force or fraud.

RECORDING INDUSTRY
The growth of the global recording industry represents a post—World War II (1939–1945) phenomenon. Despite the inventions of the radio and the phonograph, record sales remained relatively low in the first half of the twentieth century. It was not until 1948, when Columbia Records introduced the 12-inch vinylite long-playing (LP) record onto the market in the United States, that the industry enjoyed its first significant stimulus to growth. The emergence of new low-cost recording equipment followed in the 1950s and allowed many independent record labels, known as indies, to compete with the major record labels, or majors, namely, Columbia, RCA, and Decca. This provided an opportunity for a greater variety of artists to release music and increased demand as consumers exploited the wider choice of music available.

The 1960s was a creative decade in which many of the old formulas and structures changed. Hi-fi stereo recordings were first introduced, and the development of tape formats that would eventually transform the industry picked up pace in the mid-1960s with the appearance of four-track and eight-track tapes. The eight-track achieved a dominant position over the four-track until the cassette tape, introduced by the Philips Company in 1963, eventually took over in the 1970s. Cassette tapes were smaller, more convenient, reasonably cheap to produce, and, in combination with the development of accompanying compatible software, transformed the production and consumption of music.

Growth of the industry continued until the recession of the early 1980s when the demand for music fell. Many in the industry at this time believed that the availability of home cassette recorders was responsible for much of the loss in sales and there were attempts to tax blank recording cassette tapes. Yet, some analysts suggest that the decline was predominantly related to the poor quality of the recordings, inferior software, the global recession, and a shortage of creative work.

The downturn only proved temporary, however, and a period of high growth followed, largely due to recording improvements and the expanded use of digital formats, such as the compact disc (CD). Because of the low cost of production and strong market demand for high-quality recordings, record companies focused on low-risk opportunities for profit. This took the form of issuing CDs of back catalogues and compilations of works by established artists. At the same time, the development and growth of global satellite television channels catering to music lovers only, such as MTV, also contributed to an increased demand for music.

By the late 1990s, a culture of “free” music was emerging as use of the Internet expanded. In 1999, Shawn Fanning, then an eighteen-year-old student at Northeastern University in Boston, created a computer program called Napster that allowed Internet users to search for songs in MP3 format (“near” CD-quality sound) on the hard drives of other users, and then download this music to
their own hard drives at no cost. However, within only a few months of its existence, Napster was sued by the Recording Industry Association of America on behalf of the major record labels for copyright infringement. Napster lost the case, and in July 2001 was forced to shut down.

By 2004 global sales of physical recorded music (audio and video) were estimated to be $33.6 billion, representing a fall of 10 percent in real terms since 1999. Total global unit sales in 2004 were 2.8 billion, 77 percent of which were accounted for by sales of CDs. In the same year, the United Kingdom had the world’s highest per capita sales of recorded music in both volume and value terms, at 3.2 units and $58.20 respectively. The figures for the United States were 2.8 and $41.50 respectively. However, the recording industry also helps drive a much broader music sector, from subscription radio stations to mobile ringtone sales, that was estimated to be worth more than $100 billion globally in 2005. Music has an economic importance that extends well beyond the scope of record sales.

In terms of its organization, the recording industry has a highly concentrated, oligopolistic structure dominated by four majors: Sony-BMG, EMI, Universal, and Warner. In 2004 these four companies enjoyed a combined global market share of 75 percent. The remainder was accounted for by numerous indies whose continued presence reflects two factors: (1) an ability to expand markets and specialize in market niches; and (2) a reliance upon the majors to bring their music to market. One consequence of this symbiotic relationship between the majors and indies has been the reduction of potential competition. However, digital technologies and the Internet are reducing costs and barriers to entry and represent an opportunity for the indies to loosen the majors’ stranglehold on the distribution of music.

As noted earlier, the growth of Internet technology that allows consumers to download music without paying the producers represents a major challenge to the recording industry. In theory, the main concern is that the activity may reduce legitimate demand for albums as potential consumers turn to pirated versions, though it can be argued that illegal downloading may stimulate legitimate demand. For example, online “sampling” of individual songs may increase demand for full album recordings.

Most empirical work by economists on this issue suggests that the negative effects of online piracy outweigh the positive effects, that is, piracy is associated with a fall in legitimate music sales. However, history shows that technology has been responsible for the growth of the mass consumption of music and has allowed today’s superstars to earn huge sums of money compared to musicians of two hundred years ago. Like the invention of recording tape and the compact disc, therefore, the Internet is likely to ultimately result in an increase in demand for music once new business models are in place. Indeed, the success of Apple’s iTunes music store has demonstrated that consumers are willing to pay for music downloads from the Internet. Industries that do not innovate in a market economy, or inefectively compete with producers of other similar products, will decline, a rule that applies to the recording industry.

**RECURSIVE MODELS**

A system of equations is recursive rather than simultaneous if there is unidirectional dependency among the endogenous variables such that, for given values of exogenous variables, values for the endogenous variables can be determined sequentially rather than jointly. Due to the ease with which they can often be estimated and the temptation to interpret them in terms of causal chains, recursive systems were the earliest equation systems to be used in empirical work in the social sciences.

In any equation system there will be a number of exogenous variables and as many endogenous variables as there are equations in the system. Exogenous variables are those whose values are determined outside the system and that affect the endogenous variables without being affected by them. Variables that can depend on each other and on the exogenous variables are called “endogenous variables.” These are the variables whose values are explained by the equation system. (Some endogenous variables enter with a lag and are called “lagged endogenous variables.”) An endogenous variable that appears on the left-hand side of...
one equation will typically appear on the right-hand side of some or all of the other equations in the system.

A recursive model is a special case of an equation system where the endogenous variables are determined one at a time in sequence. Thus the right-hand side of the equation for the first endogenous variable includes no endogenous variables, only exogenous variables. The right-hand side of the equation for the second endogenous variable includes exogenous variables and only the first endogenous variable. The right-hand side of the equation for the third endogenous variable includes exogenous variables and only the first and second endogenous variables, and so on. Another way to put this is to say that a system is recursive if the solution for the $g$th endogenous variable involves only the first $g$ equations.

A simple example involving three endogenous variables ($y_1$, $y_2$, and $y_3$) and only one exogenous variable ($x$) would be the following system—the $\varepsilon$ represent the stochastic disturbances (if the system was a purely deterministic, mathematical one, all of the $\varepsilon$ would be zero).

$$
\begin{align*}
y_1 &= \beta_1 x + \varepsilon_1 \\
y_2 &= \beta_2 x + \gamma_{21} y_1 + \varepsilon_2 \\
y_3 &= \beta_3 x + \gamma_{31} y_1 + \gamma_{32} y_2 + \varepsilon_3
\end{align*}
$$

From the structure of this system, it is clear that there is a sequential (one-way) rather than a simultaneous (two-way) relationship between the endogenous variables. Thus $y_1$ affects $y_2$, but $y_2$ does not affect $y_1$ either directly or indirectly. Similarly $y_1$ and $y_2$ influence $y_3$ without in turn being influenced by $y_3$. Systems of equations of this kind are called “recursive” or “triangular models.” If in addition there is no correlation between the stochastic disturbances, then we refer to the system as “diagonally recursive.” Ordinary Least Squares (OLS) is an appropriate estimator for each single equation in a diagonally recursive system because it can be shown that for such a system OLS yields consistent and (asymptotically) efficient estimates. This is because in a diagonally recursive system there is no correlation between the explanatory variables in any one equation and that equation’s stochastic disturbances.

More formally, in matrix notation a system of structural equations may be written as

$$
\begin{align*}
\Gamma y &= Bx + \varepsilon
\end{align*}
$$

where $y$ is a vector of the $g$ endogenous variables, $x$ is a vector of the $k$ exogenous variables (these might also include any lagged endogenous variables), $\varepsilon$ is a vector of the $g$ stochastic disturbances, $\Gamma$ is a $g \times g$ matrix of the coefficients on the $g$ endogenous variables, and $B$ is a $g \times k$ matrix of the coefficients on the $k$ exogenous variables.

If $\Gamma$ is a triangular matrix (that is, it has zeroes in all of the cells above the principal diagonal) we refer to the system as “recursive.” This is why recursive models are also called “triangular models.”

In the case of the three equations system given above, we would write $\Gamma$ as

$$
\Gamma = \begin{bmatrix}
1 & 0 & 0 \\
-\gamma_{21} & 1 & 0 \\
-\gamma_{31} - \gamma_{32} & -\gamma_{32} & 1
\end{bmatrix}
$$

This is a triangular matrix, indicating that the system is recursive.

Define $\Sigma$ to be a matrix of the variances and covariance’s of the stochastic disturbance terms. In the case of the three equations system given above, we would write $\Sigma$ as

$$
\Sigma = \begin{bmatrix}
\text{var} (\varepsilon_1) & \text{cov} (\varepsilon_1, \varepsilon_2) & \text{cov} (\varepsilon_1, \varepsilon_3) \\
\text{cov} (\varepsilon_2, \varepsilon_1) & \text{var} (\varepsilon_2) & \text{cov} (\varepsilon_2, \varepsilon_3) \\
\text{cov} (\varepsilon_3, \varepsilon_1) & \text{cov} (\varepsilon_3, \varepsilon_2) & \text{var} (\varepsilon_3)
\end{bmatrix}
$$

If $\Sigma$ is a diagonal matrix and in addition $\Sigma$ is a diagonal matrix (so that all the covariance terms are zero), the system is diagonally recursive, and OLS is an appropriate estimator. Now $\Sigma$ will be a diagonal matrix only if the disturbances across the different equations are (contemporaneously) uncorrelated—in other words, the disturbance terms are independent of each other. If a system is recursive but not diagonally recursive, in other words if $\Gamma$ is a triangular matrix whereas $\Sigma$ is not a diagonal matrix, we describe the system as “seemingly unrelated,” and the Seemingly Unrelated Regressions (SUR) method of estimation is more appropriate (more efficient) than OLS (Zellner 1962). One reason why the stochastic disturbances might be correlated across equations is if the equations have in common omitted variables, sometimes even variables that by their nature cannot be observed. This is not an unusual situation in the social sciences.

Some equation systems are said to be “block recursive,” meaning that the recursive or triangular property applies only to blocks made up of subsets of the equations in the model. If the system can be characterized as block recursive, then the endogenous variables listed in each block of equations may be jointly determined, but the blocks of equations can be ordered such that they (the blocks) form a triangular structure (see Bodkin, Klein, and Marwah 1991 for examples).

Computer packages exist that will take a list of equations and order them in such a way that any recursive structure including recursive blocks are identified. Statistical tests to ascertain whether or not the variance-covariance matrix is diagonal are also available (see Breusch and Pagan 1980 for an example).

The technique of path analysis that features in psychology and other disciplines often utilizes a recursive system, following on the ideas of Sewall Wright (1921). However, while recursive models are easier to interpret...
than models that are simultaneous, there is no mathematical or statistical reason why path analysis has to be limited to recursive models (see Seneta 2006 and the references cited therein).

REDUCTIONISM
Reductionism is the hypothesis that science is unified by chains of intertheoretic reductions across disciplines, with theories from basic physics providing the ultimate ground. The classic work on intertheoretic reduction in the philosophy of science is chapter 11 of Ernest Nagel’s The Structure of Science. For Nagel, reduction is logical deduction (derivation) of the statements of the reduced theory $T_R$ from those of the reducing theory $T_B$. In interesting cases from science’s history, the $T_R$ contain terms that do not occur within the descriptive vocabulary of $T_B$ (e.g., equilibrium thermodynamics contains “pressure” and “temperature,” which do not occur in statistical mechanics and the kinetic/corpuscular theory of matter). Such cases are especially prominent in the psychological and social sciences because their theories developed mostly independently of one another. To derive such $T_R$ from $T_B$ in something other than a trivial fashion, Nagel insisted that the premises of the derivation require bridge principles connecting terms across the theories (e.g., “temperature in a gas is mean kinetic energy of molecular constituents”). Furthermore, most historical scientific reductions are corrective—they indicate where the $T_R$ is false. Thus Nagel insisted that the premises of the deduction must contain not only the $T_B$ and the necessary bridge principles but also various limiting assumptions and boundary conditions on $T_B$’s application, some of which are contrary to fact. These elements circumscribe the falsity in the premises of the valid derivation of a false conclusion ($T_R$) away from the (presumed true) $T_B$.

Challenges to Nagel’s account were quickly raised by philosophers of science, but virtually every alternative account of intertheoretic reduction—for example those by Kenneth F. Schaffner in 1967 and Clifford Hooker in 1981—emerged as a direct response to Nagel’s details.

With physics providing the ultimate reducing theories, reductionism is allied with physicalism about mental and social phenomena. As an explicit program, it has focused primarily on cases from biology and psychology rather than the social sciences. The rationale is straightforward: Claims about accomplished reductions in the former remain controversial, and if these controversies cannot be resolved, then the plausibility of the program for the latter seems remote. However, social phenomena do make an explicit appearance in one of the classic papers on reductionism in the philosophy of science. Paul Oppenheim and Hilary Putnam (1958, p. 7) illustrate the “working hypothesis” of the unity of science as follows:

6. ........ Social groups
5. ........ (Multicellular) living things
4. ........ Cells
3. ........ Molecules
2. ........ Atoms
1. ........ Elementary particles

Each level is related as parts (below) to wholes (immediately above), with “micro-reductions” hypothe-
sized to obtain between theories explaining phenomena at a lower and an immediately higher level. And while Oppenheim and Putnam admit that accomplished micro-reductions from levels 6 to 5 have not advanced very far, they cite individual choice theories in economics and the "principal theoretical approaches" in sociology (Marxist, Veblenian, Weberian, Mannheimian) as examples of attempted micro-reductions to individualist psychology.

One popular general criticism of reductionism focuses on the multiple realizability of given higher-level kinds on lower-level mechanisms. (Bickle’s 2006 article “Multiple Realizability” provides a survey of these arguments and many reductionist responses, with an extensive bibliography.) An example from the social sciences often appealed to is Gresham’s law (colloquially stated, that “bad money drives out good,” and more precisely stated in terms of what happens in monetary exchanges under specific exchange conditions). Monetary exchange is realized by a wide variety of physical phenomena—exchanging paper bills or minted coins or strings of wampum, signing checks, or depressing the “Enter” button on one’s desktop computer, to name just a few. It seems a safe empirical bet that no single physical kind, described and studied by some lower-level physical science, obtains in all these cases (not to mention in the myriad possible realizations of monetary exchange). One could disjoin all the lower-level realizers of such a high-level kind, but it seems an even safer bet that the resulting disjunctive kind does not occur in the explanatory laws of any physical science from which the laws of the higher-level science can be derived.

From the mid-1970s until the mid-1990s this argument held sway against reductionism. A few replies emerged during this time. Some reductionists advocated domain-specific reductions, limited to classes of realizers that shared lower-level mechanisms. Others pointed out examples of accomplished reductions from science’s history that included multiply realized kinds in the reduced theories, showing that multiple realizability is not sufficient by itself to block intertheoretic reduction. Since the late 1990s some critics have appealed to different “grains” in the characterizations of higher- and lower-level kinds. Advocates of multiple realizability tend to tolerate a wide variety of functional differences in their specification of higher-level kinds shared across distinct realizers, but they insist that a single (minute) physical difference indicates distinct lower-level kinds. When grains are matched across higher- and lower-level theories, multiple realizability vanishes. Others have noticed a dilemma for advocates of multiple realizability. The more that the physical mechanisms across distinct realizers are similar, the less likely is multiple realization of the same higher-level kind. At the time of this writing, anti-reductionists appealing to multiple realizability owe responses to these challenges.

A more diffuse anti-reductionist argument focuses on the complexity of social phenomena. Most likely it is this intuition that lies behind critiques of reductionist approaches by critics of neoclassical economics: Reducing social phenomena to the dynamics of individual decision makers will fail to explain some crucial economic or social features. (Reductionism to individuals is often characterized as “doctrinaire” or “simplistic” in the social sciences.) But turning this intuition into rational argument is not easy. One recent attempt applies the sophisticated mathematics of complexity theory to social sciences—dynamical systems, chaotic nonlinearity, trajectories through high-dimensional state spaces, and the like. Explanations in the form of differential equations are proposed to account for the behavior of systems, but not in terms of the mechanical outputs of its components. (Timothy van Gelder’s application of complexity theory to cognitive psychology is a detailed attempt of this sort.) The principal worry is whether the “reductionism” targeted here is a straw man. If the behavior of systems requires these explanatory resources, then so will the lower-level sciences that appeal not only to the structure but also the dynamics and organization of the system’s components. The philosopher William Bechtel (2001), for example, replies that complexity is compatible with reduction, in the form of decomposition and localization explanatory strategies. He argues not just on conceptual grounds but also by appealing to empirical work by cognitive neuroscientists studying memory.

REFERENDUM

A referendum is a form of direct democracy in which the entire electorate votes to accept or reject a policy proposal. Nearly all democracies in the international community provide for national referendums. Yet there is no provision in the U.S. Constitution for one. The Tenth Amendment implies that referendums are left up to the states. Because of this, states decide individually whether to allow referendums and how they are to proceed.

In the United States a legislative referendum is an election in which the state legislature passes a bill for consideration by the state’s voters for final adoption. Not all states have a legislative referendum provision for nonconstitutional issues, even though all states except Delaware allow or require constitutional amendments to be approved through referendums. Some states allow for voters to override legislation by referendum, so long as supporters gather a requisite number of signatures. This is known as the popular referendum. Twenty-four states (mostly in the American West) and myriad local governments provide for legislative and popular referendums. Referendums are similar to but conceptually distinct from initiatives. Although similar in that the people have the final say to support or oppose a policy and citizens groups may be required to gather signatures for both referendums and initiatives, referendums are a direct response to action by the legislature. Conversely, citizens, citizens groups, or other interest groups initiate the policy proposal to be placed on an election ballot.

REFERENDUMS AS PROGRESSIVE REFORMS

The history and initiation of referendums in the United States is a product of the progressive reforms. In response to the political corruption of party machines in urban areas throughout the United States, the Progressives pushed numerous reforms to depoliticize politics. Progressive reforms began with the creation of the federal civil service system with the Pendleton Act of 1883. They also included state-printed secret ballots, direct primary elections, nonpartisan elections, and initiatives, recalls, and referendums. The goal of these reforms was to wrest political control away from centralized and strong political parties and return democracy to the people. Although they had their intended effect of weakening political parties, they also contributed to a significant decline in voter participation over time. Even directly deciding policy through referendums is typically not sufficient to mobilize high voter turnout.

States vary in their use of referendum. For legislative, nonconstitutional referendums, California requires that the measure, with valid signatures equal in number to 5 percent of all votes cast in the previous gubernatorial contest, be presented to the secretary of state within ninety days after its enactment by the state legislature. The secretary of state then submits the referendum for placement on the ballot in the next general or special election, or the governor may request a special election. California’s procedure for legislative referendum is fairly typical of most other states. California used the legislative referendum process in 2000 to pass Proposition 22, which held that only heterosexual marriages were legally valid in the state. Citizens in the state of South Dakota relied on a popular referendum to overturn, or veto, a 2006 state law that would have banned abortion except to protect the life of the mother. Citizens were required to gather over 18,000 valid signatures (or 5 percent of votes cast in the previous gubernatorial race) to place this popular referendum on the November 2006 ballot. Texas state law requires that any amendment to the Texas Constitution be approved by two-thirds of both houses of the state legislature and then placed on an election ballot for final adoption by the voters. In November 2005 Texas amended its constitution in this manner by defining marriage as a union between a man and a woman. All states may place advisory or nonbinding referendums on an election ballot. These referendums have no binding policy effect but instead are consultative referendums initiated by the government, perhaps, to poll the electorate as to their general belief on an issue. It is ultimately up to the state legislature whether to embrace or ignore these results.

CONSEQUENCES OF REFERENDUMS

Although the goal of referendums and other forms of direct democracy is to allow people to decide policy, there may be unintended consequences for some of the people as a result of these popular initiatives. James Madison (1751–1836), fourth president of the United States, warned about the deleterious effects of factions, that
majority will—if left unchecked—could actually punish the minority, creating a “tyranny of the majority.” For these and other reasons, the framers of the U.S. Constitution adopted a document that was exceedingly thin on direct democratic provisions but instead provided for representative democracy.

With the institution and proliferation of forms of direct democracy as a policy tool in the late twentieth century, scholars began to explore the consequences of direct democracy and whether or not referendums or initiatives actually harm minorities. Barbara Gamble found in her 1997 article “Putting Civil Rights to a Popular Vote,” for instance, that local and state ballot measures (referendum included) typically harm minorities, and she concluded that representative democracy protects minorities better than direct democracy does. Todd Donovan and Shaun Bowler showed in their 1998 article “Direct Democracy and Minority Rights: An Extension,” on the other hand, that direct democracy is not necessarily harmful to minorities. Instead, largely populated areas with well-educated citizens tend to adopt ballot measures that actually protect homosexuals. Donovan and Bowler concluded that both direct and representative democracies have comparable limitations in protecting specific minority groups.

The claim that referendums reflect the popular will of the majority or that they provide for direct democracy in the truest sense is open to question for several reasons. First, as with most other elections, only a small and self-selected percentage of the voting public participates in referendum elections. Constitutional amendments that must be approved of through referendum may be placed on the ballot during special elections, not associated with either statewide or nationally elected office. The skew in voter participation for these referendums is likely to be especially pronounced. Moreover many of these referendums may pertain to mundane matters, such as issuing bonds for economic development or pollution control, which are not of interest to many voters. Second, large states, like California and Texas, may have too many referendums on an election ballot, which may cause voters to roll off, or not finish the ballot, actually reducing the proportion of voters who participate. Indeed the 2006 midterm election ballot used in several California counties was over 120 pages long. Third, referendums may be worded in a confusing fashion, with a “yes” vote supporting change in one referendum and a “no” vote supporting change in another. Fourth, voters may make policy based on a whim, not careful research, leading to ineffective or countereffective policies. Finally, government accountability may be reduced if citizens—not their elected representatives—are responsible for making public policy.

Unlike the United States, referendums are more central to governance in many other democracies, with numerous states relying extensively on national referendums for policy making. Switzerland’s referendum process is central to policy making, whether for constitutional amendments, legislative enactments, or according to Lawrence LeDuc in his 2003 book The Politics of Direct Democracy: Referendums in a Global Perspective, “rejective” referendums. It does not have a nonbinding or advisory referendum provision. Although Sweden provides for both binding and nonbinding referendums, most of its late-twentieth-century referendums were advisory to the legislature. Other countries use the referendum process to approve constitutional amendments (France), vote on independence (Puerto Rico), recall politicians from office (Venezuela), determine public policy directly (Brazil), or decide European Union membership (United Kingdom).

REFLECTION PROBLEM
In his extension of the identification problem to the social sciences, Charles Manski, in his book Identification Problems in the Social Sciences (1995), poses the reflection problem. The problem surfaces when one tries to predict the behavior of an individual by the behavior of the group of which the individual is a member. The problem is likened to the image of a person reflected in a mirror. The mirror can be said to reflect the image of the person's motion or to reflect the image and the person moving together consequent to an external stimulus.

The reflection problem is further explained through the variables used in a statistical model. Standard identification problems in economics use observations of prices and quantities, two endogenous variables, to reveal consumers’ and producers’ behavior. The economist would add predetermined variables to identify the demand and
supply curves. The reflection problem, however, looks at other endogenous effects that are overlooked or ignored in the standard order-and-rank identification process in economics. These additional variables are used mostly by sociologists who are concerned with how problems are reflected from society to the individual, while economists usually use social effects as constraints of individual opportunities.

Modern researchers are unable to solve the reflection problem through the modeling of output data, which cannot capture the reflection problem. One of their hypotheses might be that individuals belonging to a group tend to behave similarly. The researchers probe their models for endogenous, contextual, and correlated effects. Models with endogenous effects explain variations in individual behavior by the prevalence of the behavior in a group. Individuals behave similarly because they may experience pressure to conform to certain norms. Models of contextual effects explain individual behavior with the variation of background characteristics of the group, such as the influence of the neighborhood environment. Models of correlated effects assess whether individuals facing a similar environment or sharing similar individual characteristics will behave the same way. For example, people may associate with each other because they share similar characteristics.

Manski provides an intuitive example to explain the problem of separating these effects. A measure of the mean behavior of the group will contain the individual behavior. A measure of the outcome of a group behavior might simply be an aggregation of individual behaviors. One cannot be sure, therefore, that it reveals the individual behavior. By using the mean behavior of a group, the mean value of exogenous attributes of a group, or similar characteristics of members of a group to explain individual behavior, one captures exogenous, contextual, and correlated effects, respectively. To infer individual behavior from a measure of group behavior would require prior information that explains the composition of the group. To distinguish among these effects, it is necessary to know something more about how the groups are formed and how the members interact.

One can solve the reflection problem if one knows that the group mean influences individual behavior with a specific lag structure. Analogous assertions can be made if the researchers know a nonlinear specification, specific group features, or some instrument that conveys influences from the group to the individual. Generally, such information is not available.

**REFLEXIVITY**

Individuals, institutions, and societies are reflexive: They “turn back” upon themselves to observe, reference, describe, predict, assess and explain their own ways and workings. Reflexive turns are not mere adjuncts to social life: They make it possible and increasingly comprise its very fabric. Selfhood, mind, and agency are constituted through the human capacity to reflexively make an object of oneself. Individuals interact with one another in light of their reflexive understanding of the contexts and consequences of their actions. Innumerable professionals—social scientists among them—audit, analyze, and forecast the functioning of organizations, institutions, and the society itself. Reflexive turns, then, are implicated in the very construction of social actors, social actions, and the disciplines and professions that study and monitor them.

Reflexive turns are complexly related to the circumstances from which they emerge. First, rather than mirror a preexistent domain, reflexive turns are constitutively entwined with the form, dynamics, and even existence of what is observed or described. Self-fulfilling prophecies illustrate one way reflexive “knowledge” about circumstances affects their development. In the classic example of self-fulfilling prophecies provided by R. K. Merton in 1948, rumors of insolvency precipitate a run on a financially sound bank culminating in actual insolvency. Second, while reflexive turns may claim an objective vantage point from which to observe, analyze, and explain, they are embedded in and informed by the embodied, interactional, organizational, and cultural contexts from which they emerge. A perspicuous example of the embeddedness of reflexive explanations is provided by E. E. Evans-Pritchard’s 1937 study of Azande beliefs regarding
magic, witchcraft, and oracles. Azande explanations of the occasional failure of oracles to correctly predict future events were predicated on the cultural assumptions that contributed to belief in the efficacy of oracles in the first place. Finally, reflexive turns efface their own embeddedness and entwining. Forgetful of both their origins and contributions to what they “discover,” reflexive turns (including this description of reflexive turns) treat the phenomena they discern as preexistent independent objects and themselves as (mere) observation, revelation, or representation.

INQUIRY INTO REFLEXIVITY AND REFLEXIVE INQUIRY

The embedded and entwined features of reflexive turns are topics of social scientific inquiry. Studies of social interaction, for example, highlight how discourse and background knowledge “about” a social setting contributes to its collaborative construction. Studies in economic sociology and kindred fields identify how lay and professional economic reasoning shapes financial markets and even the reasoners themselves. In examining how economic theories are appropriated by the society, Fabrizio Ferraro, Jeffrey Pfeffer, and Robert I. Sutton in 2005 suggested that as the model of homo economicus of classical economics infiltrates the discourse, norms, and circumstances of society, individuals increasingly invoke, conform to and thereby “validate” the model intended to explain their behavior. Analysts of major sociohistorical developments suggest that “late-modern” social life is marked by unprecedented levels of institutional and individual reflexive monitoring. Modern life requires, as Anthony Giddens observed in 1991, that “the question, ‘How shall I live?’ has to be answered in day-to-day decisions about how to behave, what to wear and what to eat” (Giddens 1991, p. 14).

In addition to being a topic for social science, reflexive turns are also challenges to social science. Nourished by the sociology of knowledge and amplified by the heightened reflexivity of late modernity, a panoply of voices asserts that the social (and natural) sciences have yet to recognize the full extent of their own embedding in and entwining with the processes they study. Calls for reflexive inquiry (in contrast to inquiry into reflexivity) challenge social scientists to explicate how they themselves and their projects, perspectives, operations, and findings are embedded in a nexus of enabling and constraining relationships, presuppositions, interests, and practices whose operation and effects escape the delimited self-reflection of conventional inquiry.

Reflexive inquiry bids researchers to address themselves, their inquiries, and the inquiries’ products in terms of the processes found elsewhere in social life. On the micro level, reflexive inquiry focuses on tacit practices of categorization, interpretation, interaction, and textualization through which research is conducted. On the institutional level, reflexive inquiry examines how various contexts or fields foster intellectual dispositions and pre-judgments that form what Pierre Bourdieu in 1992 referred to as “the collective scientific unconscious” (Bourdieu and Wacquant 1992). On the structural level, reflexive inquiry invites self-examination in terms of how the process and products of inquiry are shaped by the researcher’s social location in political, economic, ethnic, or gender hierarchies.

PROBLEMS AND PROMISES OF REFLEXIVE INQUIRY

Promising to deepen and even improve research, reflexive inquiry may give rise to unsettling problems. Reflexive inquiry tends to blur the very distinctions between observer and observed and between representation and reality upon which conventional inquiry is predicated. Further, explication of the embedded and entwined features of social scientific inquiry threatens to initiate an infinite regress in which each successive reflexive turn calls forth yet another to explicate its predecessor. Moreover, reflexive inquiry may so divest itself of analytic concepts (treating them as phenomena to be reflexively explicated) that it threatens to devolve into a vacuous exercise. Finally, the extent to which reflexive inquiry can access and explicate the effaced background of research is uncertain. Unsurprisingly, social scientists vary in their enthusiasm for taking the reflexive turn and exposing themselves to these (and other) problems.

The ways persons, institutions, and societies take account of themselves are constitutive processes of social life. The social sciences are themselves reflexive turns and thus are charged not only with inquiry into reflexivity but also with reflexive inquiry, that is, with explicating their own embeddedness in and entwining with the affairs they purport to illuminate. The dividends of reflexive inquiry include insight into the constitutive role of observation, description, and analysis and the practices and prejudgments implicated in such activities. As daunting as they may be, the unsettling problems of reflexive inquiry, in the very ways they unsettle, are potent resources for discerning fundamental assumptions, practices, and limits of social science.

Refugee Camps

Refugee camp refers to a place where temporary housing is provided by governments or nongovernmental organizations (NGOs) for persons displaced from their homes due to war, political oppression, and/or religious persecution. The displaced person, referred to as a refugee, is someone with a well-founded fear of persecution on the basis of his or her race, religion, nationality, membership in a particular social group, or political opinion, who is outside of his or her country of nationality and unable or unwilling to return. A broader definition might include internally displaced persons (IDPs), those who had been uprooted within their own countries.

The basic infrastructure for refugee camps normally includes sleeping accommodations, hygiene facilities (bathrooms and showers), medical supplies, and communication equipment but the quality of infrastructure varies within and across geographic locations. The camp sites might be composed of tents, huts, or boxcar living structures. The development of refugee camps, however, is not always the result of government or NGO initiatives. Often makeshift refugee camps emerge because of massive numbers of people fleeing conflictual situations gathering in spaces that offer some greater level of personal security. At this point governments and organizations providing humanitarian assistance intervene to provide relief that might include latrines, food, medical assistance, and sleeping accommodations.

HISTORICAL DEVELOPMENT

Refugee camps are not solely a contemporary world phenomenon. One of the earliest recorded refugee camps is described in the biblical account of the Israelites’ flight from Egypt in Exodus. Moreover, throughout human history there have always existed clashes of interests that had profound implications for human suffering, forced removal from homelands, and caused displacement. The development of refugee camps, however, is associated most often with conflicts transpiring in the contemporary world. In the aftermath of World War I significant numbers of people could be categorized as refugees, but the existence of refugee camps took on global significance after World War II and has become increasingly more common since the end of the cold war.

At the end of both world wars, individuals who feared for their lives or otherwise felt threatened were likely to seek refuge by fleeing to another country. The United Nations (UN) Charter included provisions that established the UN High Commissioner for Refugees (UNHCR) in 1951. The UNHCR had a mandate to seek durable solutions for affected refugee populations through repatriation programs, integration into host communities of the country of first asylum, or resettlement in a third country. This indicates that refugee camps as they have come to be known in the early-twenty-first century were not as widely dispersed globally as they were in the late 1990s. However, one of the oldest known camps, which was created in 1948, still exists in Palestine. Internal conflicts that can be traced back to the end of colonialism have contributed to the proliferation of refugee camps in modern times. The end of the cold war also revived historic animosities and ethnic tensions leading to increased numbers of complex emergencies, increased numbers of people affected by them, and a change in the nature of population displacements that contributed to a proliferation of refugee camps. Such conflicts coupled with natural catastrophes have created a global challenge and make clear the need to ensure that people worldwide enjoy security and freedom.

Melvin Pollner

Melvin Pollner
TWENTY-FIRST CENTURY PERSPECTIVES

According to the 2005 World Refugee Survey, there were more than 11 million refugees worldwide and more than 21 million IDPs as of December 2004. Not all refugees live in camps, and it is difficult to obtain reliable data pertaining to the actual number who do. In some cases, refugees permanently settle in the host country and integrate into the communities in which they live. In other cases, it is difficult to distinguish between what constitutes the refugee camp, camps for IDPs, and normal housing for a given area. Even so, providing basic accommodations for refugees, as well as IDPs, is a problem that demands global attention. The number of refugees and IDPs associated with ethnic conflicts—such as those in Rwanda in 1994; the Sudan from the 1980s to 2006; East Timor; Kosovo in the 1990s; Afghanistan; and other Third World countries—led to the establishment of refugee camps such as those in Musasa in Northern Burundi; Mboki in Central Africa Republic; Darfur, Sudan; Karama in the Democratic Republic of Congo; Kupang in Indonesia; and Kelli Fazo in Pakistan, which are some of the most populated sites.

Despite enormous efforts by the UN, host governments, and NGOs to render these and other refugee camps livable, conditions have ranged from bearable to horrendous. Some lack very basic supplies such as potable drinking water, latrines, medical supplies, and ample food. Diseases are widespread; many of the children lack access to medical care of any kind and schooling can be unavailable or inadequate; and some refugees live under the threat of forced removal from camps. Although refugee camps tend to be set up near border areas, away from conflicts, many are subject to violence inflicted upon the inhabitants by government forces and/or insurgents on both sides of the border.

One of the greatest threats to peace and security in the twenty-first century is the large-scale movement of refugees and other forced migrants stemming mostly from internal conflicts and natural catastrophes. Failure to address the problem may lead to greater ethnic conflict within countries and across borders, the uncontrollable spread of disease, and greater environmental degradation. Given that Third World nations hosting refugees have challenges in terms of meeting the needs and demands of their own citizens, industrialized nations must step up their efforts to address the problem. In addition to providing financial and humanitarian support, these nations must pressure governments to observe human rights; demonstrate a stronger commitment to timely diplomatic intervention, as a first step, to avert conflicts that are likely to increase the refugee population; and revisit restrictive asylum policies that came to fruition during the 1980s.

REFUGEES

Refugees are a subset of immigrants often termed political migrants. They are pushed out of their homelands, typically by war or government persecution due to religion, ethnicity, or political activism. For example, Albert Einstein (1879–1955), often considered the most influential scientist of the twentieth century, was among the Jews who left Germany during the 1930s due to Nazi anti-Semitism. The Buddhist monk His Holiness the Dalai Lama is an internationally recognized advocate of human rights for Tibetans; he fled Tibet in 1959 following the brutal crackdown by China against Tibetans opposing Chinese rule.

In contrast to refugees, most immigrants are pulled from their homes by the prospects of better jobs in other countries, or to join family members who already reside abroad. These economic and social forms of international migration allow time for a considerable amount of planning and preparation. Such immigrants often believe they will return to their homelands at some point in the future. Refugee migrations, however, are unanticipated and forced, and will keep the émigrés away from home for a very long time, possibly for the rest of their lives.

Since the mid-1990s the world has averaged between 11 million and 15 million refugees per year. The majority are women and children. The United Nations (UN) first defined a refugee in 1951 as a person who “owing to a well founded fear of persecution for reasons of race, religion, nationality, membership of a particular social group or political opinion, is outside the country of his nationality and is unable or, owing to such fear, is unwilling to avail...
himself of that country." This definition is contained in the 1951 Convention Relating to the Status of Refugees, which was developed in the aftermath of World War II (1939–1945) and only pertained to people in Europe. The 1967 Protocol Relating to the Status of Refugees broadened the policy to include people in the rest of the world. Today there are five refugee populations numbering 500,000 people or more: those from the former Palestine, Afghanistan, Iraq, Myanmar (Burma), and Sudan.

The 1951 convention and the 1967 protocol establish the rights of refugees in exile, including the rights to protection, movement, and work. They specifically prohibit refoulement—the forced return of refugees to a country where they would be persecuted. One hundred forty-five countries have signed the convention and/or the protocol, but forty-four countries, including India, Pakistan, and Indonesia, have not. Some governments use the UN definition of refugee in their national laws, as the United States did when it passed the landmark Refugee Act of 1980. Nonetheless, foreign-policy interests often determine to what degree signatories of the convention and protocol actually abide by them. The U.S. government historically has given a very favorable reception to political migrants from Cuba, but uses the U.S. Coast Guard to interdict those leaving Haiti.

There have been several global trends in refugee migrations since World War II. European decolonization produced intense ethnic conflict in newly independent states in Africa and Asia (e.g., the 1947 partition of India), and it was a major cause of refugee crises from the late 1940s through the 1960s. The cold war between the United States, the former Soviet Union, and the client states of each superpower was the main cause of refugee crises from the 1960s through the 1980s. In the United States the best known cold-war refugees are the Cubans and the Vietnamese.

Since the 1990s a new cause of refugees has been the total collapse of national institutions in some countries (termed failed states), leading to perpetual social conflict and disorder. This occurred in Somalia during the early 1990s, and other countries in Africa have followed this same pattern. In the western hemisphere, Haiti shows many signs of being a failed state and Colombia has some symptoms as well. Two catastrophic ethnic conflicts occurred almost simultaneously in the mid-1990s: More than 1 million Bosnian refugees fled Serbian ethnic cleansing in Bosnia, and about 2 million Hutus fled Rwanda when Tutsi forces regained power following the genocide of some 800,000 Tutsis at the hands of Hutu militias.

The UN High Commissioner for Refugees, created in 1950, is the primary international body charged with advocating for refugees and providing them with assistance. Many nongovernmental organizations (NGOs) also assist refugees, such as the U.S. Committee for Refugees, U.S. Catholic Conference, and Médecins Sans Frontières (Doctors Without Borders). NGOs lobby states for more favorable policies, provide services in refugee camps, and facilitate adaptation when refugees resettle in host countries or repatriate to their homelands. But refugees often endure years of waiting in impoverished, segregated camps, a situation termed warehousing. If the root political problems remain unresolved for a long time, warehousing creates multigenerational refugee populations. Nearly 2 million Afghani refugees reside in Iran and Pakistan, a legacy of the Soviet invasion in 1979 and subsequent wars. About 2.5 million Palestinians throughout the Middle East receive assistance from the UN Relief and Works Administration for Palestine Refugees. The Palestinians were originally displaced by the wars that followed the creation of Israel in 1948.

An important legal distinction for political migrants is whether they seek refugee status before or after arriving in a host country where they hope to permanently reside. The United States, Canada, Australia, and the countries of the European Union allow people with a well-founded fear of persecution to apply for entry while still living in their homelands or in adjacent countries to which they have fled. Since passage of the Refugee Act of 1980 the United States has accepted more than 2.5 million refugees in this way. Congress and the president establish an annual refugee admissions quota, and refugees who arrive are eligible for social welfare programs operated by the federal government, state governments, and NGOs. Since 2000 the former Soviet Union, Somalia, and Iran have been the leading source countries of refugee admissions to the United States.

Actual or imminent persecution can be so dire that people flee without waiting for permission to resettle in a host country. When political migrants cross into another country without legal authorization and then apply for refugee status they are called asylum seekers. China, Haiti, El Salvador, and Guatemala are the sources of about 45 percent of all asylum seekers who have entered the United States since 1989. In western Europe most asylum seekers come from Turkey, Africa, and the Middle East. The United States and other western countries use legal proceedings, which often are hasty and haphazard, to determine whether asylum seekers have credible reasons to fear persecution if deported to their homelands. U.S. asylum officers approve fewer than half of all asylum requests. U.S. immigration judges adjudicate claims initially denied, but the success rate of these appeals is even lower.

People who flee persecution but stay within their native country rather than crossing an international bor-
under share many of the same experiences as refugees. They are termed *internally displaced persons* (IDPs). The term *displaced persons* gained prominence in Europe after World War II, when it was used to describe Poles, Germans, and other people who were outside their homelands due to the war; in some cases they did not wish to return home. IDPs now is used to refer to people who have fled persecution or war but who cannot avail themselves of the 1951 convention or the 1967 protocol because they are still within the jurisdiction of the state which regulates their citizenship.

There are more IDPs in the world than refugees: about 25 million compared to 11.5 million. Five countries have more than 1 million IDPs: Sudan, Colombia, Uganda, Congo-Kinshasa, and Iraq. International protection and aid for IDPs conflict with national sovereignty and requires asserting that a state is unwilling or incapable of protecting its own citizens. For a brief period during the 1990s the UN undertook such humanitarian intervention in northern Iraq, Bosnia, and Somalia. Unfortunately, the humanitarian crisis that began in 2003 in the Darfur region of Sudan did not produce a similar response from the international community. In 2005 the UN adopted guidelines for assisting internally displaced persons by creating a division of labor among its various agencies. Social scientists are divided over whether or not to extend the concept of IDPs to the survivors of catastrophic natural disasters, such as the South Asian tsunami in 2004 and Hurricane Katrina on the U.S. Gulf Coast in 2005. Many of the people displaced by Hurricane Katrina were offended when the media described them as “refugees,” believing that the label equated them with “foreigners” who did not merit the protections granted to “citizens.” Whether to use the term *environmental refugees* to describe people who flee the environmental problems caused by deforestation and global warming is also a matter of debate.

There are two solutions to a refugee crisis. Voluntary repatriation occurs when homeland conditions have improved and the refugees return from abroad. They require economic development assistance similar to that provided for other projects in the developing world. Resettlement in the United States, Canada, Australia, and the European Union is a second though less frequent outcome for refugees. Resettled refugees share with other immigrants many of the same adaptation challenges, such as acculturation and finding employment. But refugees have some distinct adaptation concerns, including mental health problems and often a particularly intense interest in homeland politics. Given the trauma of forced migration, it is not surprising that refugees carry lifelong vestiges of their experiences.

**REGGAE**

Reggae is a complex Afro-Jamaican twentieth-century musical phenomenon that has profoundly influenced global popular musical culture. As a genre of modern black cultural production, reggae music dates from the 1970s, when it emerged from the musical confluence of ska and rock steady, two forms born in early postcolonial Jamaica. As a cultural practice in Jamaican postcolonial society, reggae was closely tied to subaltern representations of slavery, colonialism, history, and Africa. As a consequence in many instances reggae became a counter-hegemonic practice critiquing the formal Jamaican Creole nationalist project of political independence.

Ska was a 1960s musical synthesis that ruptured the Jamaican musical form known as *mento*, which emerged from the encounter between European colonialism, racial plantation slavery, and the slave African population. Mento adapted and morphed the harmonic structures, instrumentation, and melodies of European musical styles into indigenous sounds. It added other instruments, in particular rhumba scrapers and drums, and wove melodic structures within the sound of the rhumba scraper to produce a unique rhythm to which many rural Jamaicans enjoyed dancing.

Profoundly influenced by African American jazz and big band swing music, ska broke with mento in two ways. It used different instrumentation, and it became an urban-based rather than a rural-based musical form. Ska
was driven in part by two migratory patterns: the external migration to the American Eastern Seaboard and the internal migration between the island’s rural areas and the capital city Kingston, where impoverished young men and women not only wanted to carve out a future but also brought with them the culture of the rural folk. Particularly in Kingston’s western sections—Jones Town, Trench Town, and Denham Town—postcolonial popular Jamaican music found its moorings. This rural-to-urban shift in Jamaican society is visually captured by the opening moments of the film *The Harder They Come* and Jimmy Cliff’s driving lyrics of the song: “You can get it if you really want.”

In addition to ska, the cauldron of west Kingston gave birth to the sound system, the early recording industry, rock steady, and eventually to reggae. The Folkes Brothers’ 1961 record *Oh Carolina* marks a watershed in Jamaican recorded music. With the Rastafarian nyabinghi-style drumming of Count Ossie forming the spine of the track, the song is now a classic of Jamaican music. Although ska incorporated big band horn-blowing elements, it differed from jazz and swing in the way Jamaican musicians sped up the second beat while slowing down the fourth, so that the music seemed offbeat with loose skips. One of the most important ska instrumentalists was the trombonist Don Drummond, who played with the Skatalites, perhaps Jamaica’s most accomplished musicians at the time. This group produced such titles as “Freedom Sounds,” “Far East,” “Addis Ababa,” and “Man in the Street,” indicating the tight relationship between urban poor communities in Jamaica and Africa and certainly the cultural importance of Rastafari. The music of the Skatalites remains a rich archive of early Jamaican music.

Jamaican music is organically tied to dance and the body. There is no popular music without dance steps. In the history of Jamaican music, with its reliance on the local sound system as the conduit of its popularity, the participation of both audience and dancers in giving the music its form is critical. When the audience comprises primarily urban dwellers alienated from official society, then the relationship among the music, musicians, form, and audience becomes especially intimate and can become a practice of counter-signification. This practice is clearly illustrated by the morphing of ska into the musical form of rock steady. If ska began as the music of hope, it quickly came to express a growing alienation and despair, as “Simmer Down,” the single most important ska hit of the Wailers, illustrates. In the song the Wailers ask the “rude bwoy” to “simmer down.” The “rude bwoy” was the iconic young black male of the city, a figure of rebellion who began to confront notions of Jamaican citizenship and respectability. Prince Buster, the Nation of Islam producer and singer, also sang in “Judge Dread” of the confronta-

tion between the Jamaican justice system and the “rude bwoy.” These songs were not reflective of but rather an integral part of Jamaican social and political discourse of the period.

In rock steady, the transitional music between ska and reggae, the music slowed down, lost its skip, became languid. The dance movements were transformed, with the shoulders and hands operating in different time from the motions of the pelvis. Singing groups were central to this style; the Wailers, Heptones, Ethiopians, Paragons, Melodians, and Mighty Diamonds were popular. Singers like Jimmy Cliff, Alton Ellis, Delroy Wilson, and Ken Boothe also emerged, and along with the centrality of the sound systems of Sir Coxsone and Duke Reid and Prince Buster, Jamaican popular music consolidated itself locally. The singers and instrumental creativity of ska and rock steady combined with the creative musical drives of the urban dispossessed population to lay the ground for reggae.

In reggae the drum and bass became pronounced and the individual singer was given more scope; the horns surround the bridge segments of the music, and the dancer skips and moves with feet free from the thralldom of post-colonial oppression, while the body retraces the memory of the Middle Passage. Reggae music relies heavily on the message it delivers—from Marley’s “Trench Town Rock” to Junior Byles’s “Fade Away” and perhaps that most reproduced of all reggae riddims, the rhythm of the Abyssinians, “Satta Massagana.” Reggae music operates in the languages of black struggle and redemption and is shaped by the language—what Velma Pollard calls “dread talk”—and religious and political doctrines of Rastafari. Dread talk undertakes the lexical reorganization of Jamaican language in an effort to linguistically reorder society. The themes of reggae music are history, slavery, Africa, and exile alongside the machinations of record producers. These themes are lyrically enunciated in the idioms of proverbs, rereadings of biblical passages, Jamaican folksongs, and children’s songs. The lyrical rhetorical strategies of many reggae songs are embedded within the social and linguistic complexities of Afro-Jamaican life. One only has to listen to the vast musical archives of the Black Ark studio of Lee Scratch Perry, of Channel One Studio operated by the Hoo-Kim brothers, and of Gussie Clarke to understand how reggae presented alternative narratives of Jamaica’s history and postcolonial society. As the reggae producer Rupie Edwards put it, “The music was a way of life, the whole thing is not just a music being made … it’s a people … a culture … it’s an attitude, it’s a way of life coming out of the people” (Bradley 2000, p. 1). Marley put this well another way in the song “Trench Town”:

Whoa my head
In desolate places we’ll find our bread
And everyone see what’s taking place …
We come from Trench Town
Lord, we free the people with music. Sweet Music.

For many reggae musicians, Jamaican postcolonial society was, in the words of the Rastafari and reggae singer Johnny Clarke, a “Babylon system” that the Jamaican people had to move out of. History was a “stench” that consisted of “old pirates,” and freedom was possible only through some sort of revolution or redemption. Reggae music became the voice of black prophetic criticism in postcolonial Jamaican society. At the international level reggae has produced many iconic figures, with Marley being the most popular. Many factors shaped both Marley’s Jamaican and international appeal: the rise in Jamaican radical nationalist politics driven by conceptions of black power, the anticolonial struggles in Africa, the civil rights movement in the United States, and the failures of the immediate Caribbean postcolonial state to deliver on the hopes and aspirations of political independence. In the last stage of Marley’s life, his concert for the guerrillas of the Zimbabwean anticolonial struggle illustrated the deep connections between reggae as a popular antihegemonic musical form and aspects of international black struggles. This dimension of reggae is now being practiced by reggae poets like Mutabaruka.

Reggae continues to develop in the twenty-first century. One genre, roots reggae, popularized by the singer Luciano, distinguishes itself by its message of openness, its rebellious quality, its firm affirmation of Rastafari, and a central preoccupation with social and political issues. Other genres are dub and dance hall. In the 1970s many children of Jamaican immigrants to the United Kingdom, often called “black British,” deployed reggae as a cultural form not only of identity but of protest. Bands such as Steel Pulse and Aswad played a role in the black cultural politics of the United Kingdom. Thematically these bands reflected on the concerns of the black British experience as part of an international black experience. It was from this experience that one of the most important reggae poets, Linton Kwesi Johnson, emerged. Johnson’s poetry, as Fred D’Aguiar put it, is “an epicure of this familiar metre and rhyme served up into a reggae rhythm” (Johnson 2002, p. xi). Reggae has come to constitute an aesthetic form for many Caribbean poets.

Reggae still shapes black popular music around the globe, with reggae bands in Africa, Europe, and Latin America. In addition the philosophy of Rastafari, which traveled with reggae, remains an important cultural and social movement in many parts of the world. Perhaps the best summary of the importance of the historic achievement of reggae is that given by Count Ossie, the drummer and Rastafarian personality, who remarked that both reggae and rasta were “fighting colonialism and oppression but not with guns and bayonet, but wordically, culturally” (Bogues 2003, p. 192). Reggae as a black cultural achievement is an integral element of late-twentieth-century efforts of former colonized people to achieve full decolonization.

Regions

Regions
Social scientists looking for an organizing principle with which to understand a large area of social life have long employed broad concepts aimed at integrating complex observations and categories of social behavior. One such concept that has demonstrated broad utility is that of regions. Its application has been great in sociology, history, political analysis, economics, geography, and anthropology. In turn, each of these disciplines has contributed something to the understanding of regions.

During the first half of the twentieth century the study of urban sociology grew strongly, and a major center of this research and theorizing was the sociology department at the University of Chicago. Scholars such as Robert Park, Ernest Burgess, Louis Wirth, and Roderick D. McKenzie developed innovative research projects and interpretations of the human community. Their emphasis overall was on the urban community, and a significant aspect of their work elaborated an ecological conception of the region as an extension of the study of the community.

The ecological approach studies human beings as organisms adapting to a physical environment. Using concepts originally developed in plant and animal ecology, these sociologists focused on the spatial patterns and social organization of the community that resulted from competition for space and available resources in a geographical locale. The approach became distinctively sociological through its focus on social organization, role specialization, population concentration and centralization, and interdependence resulting from differing economic activities. Age and sex distributions are affected by ecological interactions, as is the distribution of various groupings by ethnicity and race. These stratified orders are a salient aspect of the social organization of the human community, and a significant source of these patterns lies in the realm of ecological relationships.

This approach has significant ties with demography, or the statistical study of human population aggregates, and human geography, particularly economic geography, with its attention to the physical factors that determine strategic points of location for commerce and industry. Human ecologists devote great attention to concentration, or increasing density of a population in an area, which often becomes regional concentration. Thus, regional development has its origins in population growth and movement and the tendency of people to concentrate.

Types of Regions
The classic conception of the region as taking one of four forms was developed by Louis Wirth, a prominent member of the Chicago school of sociology. His scholarship approached the region as an area distinguished by physical characteristics, such as the type of soil, annual and seasonal amounts and patterns of rainfall, length of growing season, crops grown, and border contours. Here the region is a recognizable physical area in relation to human activities carried on within, or limited by, the contours of the place inhabited or utilized. Wirth continues his analysis of the region by giving attention to areal variations in cultural features of the people who make the region their home. Cultural attributes such as language or local dialects, distinctive religious beliefs and practices, customs in dress, architectural patterns, and unique customs and forms of social organization are considered here. He concludes that either natural areas or cultural areas comprise regions, due to the homogeneity of specific features.

Wirth distinguishes a second form of region set off from other areas by physical features that serve as barriers to migration. These barriers may be mountain ranges, deserts, lakes, rivers, and oceans, or large protected valleys. He also viewed barriers created by human beings as equally powerful. These can include state and national boundaries as well as trade and custom regulations that inhibit or prevent contact between geographical locales and operate to limit the activities of an area and isolate it from surrounding areas.

The third form of region analyzed by Wirth emphasized the interdependence of activities in an area. Activities and units of organization are not homogeneous or necessarily similar, but are integrated as a way of life. This third pattern is likely to involve a trade area with a network of economic linkages with multiple radii of influence extending from a trade center outward. Examples of this third variation of the region are political capitals, cultural centers, colonial primate cities, and in the modern era, the metropolitan region with its urban center. These forms of centered regions frequently have fewer discernible boundaries, with the periphery gradually shading into a vast hinterland, or in some instances, a borderland receiving influence from a competing center or area of dominance. This third form of the region is likely to be less bound by local traditions and is likely to be dynamic, with the life activities of the region’s inhabitants in flux.

The fourth type of region is referred to by Wirth as an administrative region or ad hoc region. It often develops in an attempt to control some human problem such as crime, traffic, slum life, or contagious disease. Units of administration are created in order to ameliorate or, at minimum, set limits to the growth of one or more problems of a community. The planning region is likely to take form in a manner that does not coincide with a “natural” or physically bounded area. The New York Port Authority and Tennessee Valley Authority serve as illustrations of this fourth form of the region.
It should be noted that each of these types of region involves an areal and a spatial dimension in relation to the distribution of people and social behavior. The organized social behavior of human beings is analyzed in terms of location and position in some form of physical, cultural, or social utilization of space. Wirth cautions that none of the conceptions of the regions implies a form of geographical or physical determinism. Soil and atmosphere do not determine culture and social organization. In contrast, soil and atmosphere do not determine culture and social organization. In contrast, some of the previous writings on regionalism took physical determinism for granted and might have reflected earlier viewpoints asserting a close connection between habitat and economic and political activity.

**REGIONAL RIVALRY AND CONFLICT**

The concept of the region should be clearly separated from sectionalism, which implies organization and political consciousness based on the economic and political interests of a geographical area in a nation. In the United States, and during periods in the history of some European nations, sectional interests have been based on the natural resources of a geographical region. Historical interpretations of sectionalism incline toward a form of economic determinism. The presence of sectional interests and consciousness do point to the manner in which regional organization, and the similarity of a region’s qualities, can lead to conflict between regions. The American Civil War was an extreme example of sectional conflict based in part on regional conflict and differing economic interests, along with differing culture and way of life. Regional differences in ethnicity and racial identification, industrial development, types of agriculture, interests in tariff and trade policy, and military traditions were involved in a regional conflict of catastrophic proportions in the War between the States. A result was long-term domination by the North over the South in political and economic relations that followed the conflict.

There is no shortage of conflicts in the world at large in which regional differences play a large role. The domination of Tibet by China is a striking example in Asia. Through centuries the strategic location of Tibet between East, South, and Central Asia made it a focus of contention between more powerful rival empires. Nonetheless, its extreme difficulty of access enabled Tibet to live in isolation through most of its history. It was governed by a series of aristocratic families and became the religious center of Lamaistic Buddhism.

After the victory of the Chinese Communists over the Nationalists in 1949, the victors announced plans to “liberate” Tibet and secure China’s “traditional boundaries.” The Peking government acted on its threat in 1950, attacking in Eastern Tibet. After appeals for support that were ignored or rebuffed, Chinese terms were accepted in 1951. Chinese sovereignty was recognized, in exchange for assurances of broad Tibetan autonomy. The Chinese soon widened their administrative control and in response Tibet’s people rose up in revolt in 1956, and again in 1959. After the Dalai Lama was forced to flee to India, the Chinese crushed the rebellion. In 1965 Tibet became an “Autonomous Region of the People’s Republic of China.” This sequence of events represents an example of a more powerful nation exerting domination over a smaller, less powerful region near its border.

Governance in Spain represents another illustration of strains between regions within a nation containing historical regional-based divisions in language and culture. A part of the basis for representation is regional variation in interest. At the beginning of the twenty-first century, Spain’s senate, composed of 256 members, includes 46 members chosen by regional governments. Earlier, during the 1980s, Catalonia and the Basque Provinces had begun asking for greater autonomy, as well as the official use of Catalan and the Basque languages in their respective provinces. The Basque separatists were defeated politically in 1994. When the major Catalanist terrorist group renounced violence in 1991, Catalonia’s president was given an influential position in the Spanish government.

Italy represents another example of a nation with major regional divisions based on natural resources, economic development, local custom, and dialects, as well as other regional subcultural differences. In this case, the northern region of Italy is largely dominant over the south.

Northern Italy includes the Italian Alps, a northern plain, and the region of Liguria, on the steep and narrow coastline of the Ligurian Sea. The northern plain of Italy, south of the Alps, is an extended lowland that benefits from an abundant water supply from rainfall and the region’s rivers. Summers are long, farmlands are fertile, and there is a heavy concentration of industry. The large city of Genoa provides services to the industries of Lombardy, as well as hosting local enterprises that include chemical firms, shipbuilders, and oil refineries. Genoa’s oil pipelines penetrate into Switzerland and Germany.

Central Italy includes the regions of Tuscany, Umbria, Latium, and Marche. This area has contributed very strongly to Western civilization. The peninsula is highly urbanized, with centers such as Rome, though industry is not highly developed. Farther south, the islands of Sicily and Sardinia have no notable resources; their terrain is rugged, and droughts as well as floods are frequent. These islands are also physically more isolated, and despite attempts at development following World War II, industrial growth has been slow. These conditions have meant that economically, the north of Italy has been dominant, with population migration more frequently
directed at the northern cities. Social mobility has increased in recent years with population movement from villages into cities, and particularly from the south to the more industrialized north.

World development can also be seen from the perspective of large regional variations in industrial development and political influence. Colonialism has had an overarching influence on large world areas. European influence in North America, New Zealand, and Australia resulted in the domination of small groupings of traditional hunters and gatherers, or in some instances, pastoral societies. European settlements became dominant, and long-term colonial administrative relations were established. In large areas in southern portions of the globe—in Africa, Asia, and South America—the autochthonous, or native, populations remained numerically predominant, but under colonial rule.

These latter areas have experienced much slower industrial development than North America, the Western and Northern European capitalist centers, or Australia and New Zealand. In recent years, conditions in some of the impoverished regions of the South have actually deteriorated. Poverty is extremely widespread in the former colonial areas: In the year 2000, an estimated 1.5 billion people, nearly a quarter of the world’s population, lived in poverty in developing countries around the world. An estimated half of the global poor live in Asia, and around one-third live in Africa, with many of the remaining portion of the world’s impoverished people living in Central and South America. These statistics are now frequently seen as reflecting a worldwide division between North and South—a division that is perhaps world history’s greatest regional variation, with the largest human consequences.

Kenneth N. Eslinger

REGIONS, METROPOLITAN
At the beginning of the twentieth century it was widely recognized that the frontier in the United States had passed and that the new growth in population was in and around cities. As rural counties lost population and cities became centers of nonfarm employment, students of social behavior in North America saw a trend toward the development of larger cities. What was not immediately apparent was that the trend toward urbanization and larger cities would continue within another significant trend. This other trend was the centrifugal movement of population around large cities as the urban population, including both older urban dwellers and newcomers, would begin to move outward around larger urban places. This new trend was one of metropolitan development in contrast to merely urban growth, and it carried with it strong changes in population distribution first toward the periphery, then well beyond the boundaries of central cities.

The growth of the metropolitan region was a major social pattern during the entire twentieth century and has continued into the twenty-first century. Roderick D. McKenzie was the first urban sociologist to recognize and call attention to the national trend of metropolitan regional growth in his 1933 book, *The Metropolitan Community*. This growth pattern involves the ecological process of concentration of population in cities, combined with locally significant deconcentration into nearby areas around cities and their outlying areas. Associated with these demographic and ecological tendencies is an accompanying centralization of administrative control in urban areas, which results in a large-scale regional integration of occupational opportunities. Business decisions, employment, governmental services, shopping and consumer behavior, and a range of recreational and other quotidian
activities spread in interlinked fashion over an enlarged regional area.

The major source of the expansion of urban influences into outlying spaces, creating a region of metropolitan impact, is the reduction of the "friction" of space by reducing the limiting effects of time and distance. The enhanced speed and flexibility of motor-vehicle travel has now enlarged the radius of one hour of travel time to thirty miles or so. In the nineteenth century with horseback travel and horse-drawn wagons, this distance was closer to six miles. On foot, an hour's walking is around three miles. Few people will commute distances that require more than an hour in travel time. The effect has been to expand the square miles of space with urban influence from travel, including shopping, from around thirty-six square miles to two thousand to three thousand square miles or even more. This much greater separation of residence from work, and of errands and shopping areas from residences, has greatly expanded the metropolitan influence into a larger area. Railroad travel between cities in the latter half of the nineteenth century, followed by motor truck transport after the 1920s, have expanded the metropolitan impact to entire regions.

For purposes of clarification and definition, the terms metropolitan community or metropolitan areas are used to refer to the city and the immediately surrounding countryside, usually within a radius of twenty-five to thirty miles. Metropolitan region is the term used to refer to the much broader area, which includes a multiplicity of scattered activities that have come under administrative influences and even supervision of the large central city, or metropolis.

THE GROWTH OF METROPOLITAN REGIONS
The widely observed trend in modern societies toward large-scale social organization and greater economic reach is a fundamental source of the growth of regions and the great expansion of the metropolitan community. This pattern of growth has developed over about the last hundred years and has been documented for that length of time in the U.S. Census. These changes follow the great redirections in time and cost of movement that motorized vehicles traveling on hard-surfaced roads provide. The telephone, radio, and television followed improvements in transmitting electrical power and made possible the expansion of urban community boundaries. More recently, the computer has facilitated instant communication of information and speeded economic transactions in a manner that reduces the importance of traditionally recognized community boundaries.

The growth of a metropolitan region occurs through ecological processes that involve transportation and contact and exchange, typically in connection with distributive functions arising from various sustenance activities. A center with specialized functions and an involuted administrative organization may be the coordinating base for a hierarchy of socially connected but dispersed activities. The boundaries of a region may be set by the points of intersection of interregional routes. The size of the metropolitan center and spacing of coordinated service functions influence the emerging regional pattern. Interregional nodes of transportation may determine the early development of regional boundaries. It should be added that extractive industries as well as manufacturing exert an eccentric or decentralizing influence on large metropolitan urban locations. Continued expansion of population along with a widened range of administrative organizations extends economic activities over a larger territory.

The U.S. Census Bureau began recognizing metropolitan areas with impact on a nearby region as early as 1910. At that time approximately one-third of the population lived in these newly recognized urban "metropolitan districts," as they were known. Before midcentury they were named Standard Metropolitan Statistical Areas. Today these metropolitan areas are known as MSAs, or Metropolitan Statistical Areas, the change in designation having been made in 1983. Approximately four out of five people in the United States now live in these metropolitan areas.

A review of population data on metropolitan areas in the United States shows a long-term but massive shift outward from central cities in metropolitan areas as population moves in a large-scale pattern of decentralization into suburbs and adjacent regions. This movement of people and industry was one of the great social trends of the twentieth century, comparable to the decline of small farms and self-employment during the first half of the twentieth century, with the consequent migration to larger towns and cities. A third major social pattern, that of married women entering the labor force and remaining in the workplace after the birth of children, began to develop strongly after World War II and remains a vigorous trend. A visible effect of this tendency toward metropolitan decentralization is the high proportion of Americans who maintain suburban and exurban residences, and in moving even farther outward, contribute to the large-scale growth of urban sprawl as population continues to spread into more distant areas of metropolitan regions and beyond.

Currently, urban life in the United States, viewed demographically and ecologically, has become a metropolitan way of life, with day-to-day activities and living arrangements occurring in a continually growing multi-centered region. The metropolitan center is actually replacing the city itself as the most significant urban unit.
Whereas the first half of the twentieth century had seen a little heralded emergence of a larger metropolitan unit dominated by a central city, the later twentieth and early twenty-first centuries have seen the growth of deconcentrated populations with a multicentered pattern of growth over entire regions. These major changes have been fueled by the spread of the private automobile and the use of motor truck transport in combination with the national interstate highway systems begun in the late 1950s. Quite influential at the level of individual consumers and families have been federal tax laws that provide for mortgage interest income-tax deductions. The effect has been to subsidize middle-income families in the purchase of affordable single-family dwellings. The dearth of city lots in central cities combined with lower-cost land in rural and developing suburban areas created a potential for large-scale suburban growth and even rapid, leapfrog-style exurban development.

Scholarship in human ecology has assumed consumer demand and improvements in transportation technology as vital in reducing the critical time and distance factors prominent in urban location theory. More recent scholarship in urban sociology and urban ecology has pointed to the strong role of real estate development promotions as well as the interactions of business and local government elites in facilitating the growth of the suburbs and a continuation of the sprawl pattern around urban areas. Thus, a newer trend in urban research and scholarship emphasizes supply-side activities and real estate developers, in cooperation with banks and lending organizations, combined with government subsidies of various kinds in producing the spatial patterns of suburbs around Metropolitan Statistical Areas. All the while, continued belief in seemingly endless supplies of cheap fossil fuel for motor vehicle transportation and maintenance have contributed an ideational support for the continued growth of suburban housing and shopping malls.

METROPOLITAN CHANGES IN EMPLOYMENT AND CONSUMPTION

In metropolitan areas of the United States, there are more than three suburban residents for every two residents of the area’s central city. This trend has been growing for nearly a generation as industrial cities have lost manufacturing jobs that were often unionized with high pay and benefits, along with other lower-paying entry-level jobs that might have been filled by younger workers and poorer urbanites. As early as the 1980s, nearly twice as many people were employed in manufacturing in the suburbs than in the cities. Interestingly, since the 1980s, the typical commuter’s trip to work has been from suburb to suburb rather than the more traditional suburb to city, or earlier, urban neighborhood to city factory by foot, bicycle, or streetcar, or automobile.

Retail sales of various types, including major department stores, were concentrated in downtown locations until the 1970s. A decline in this concentration had started as much as a decade or so earlier as urban-based manufacturing and businesses as well as retail activity moved from central city locations to outlying areas, typically following highway arteries and suburban housing development. These changes in retail location and activity are seen most clearly in the growth of shopping malls. Only a few malls existed in the 1950s. Today there are more than forty-five thousand shopping malls of various sizes in the United States.

SOME CONSEQUENCES OF POPULATION CHANGES IN METROPOLITAN REGIONS

In the United States in the early twenty-first century, over half of the population lives in suburban areas. In the metropolitan areas of the nation, more than 60 percent of the population lives in the suburbs. Not surprisingly, the suburban areas have increasingly taken on an urban character in the social and cultural attributes of their populations. This is seen structurally and demographically in changes in social-class composition and increased numbers of minority group members in the suburbs of metropolitan areas. Working-class and industrial suburbs are a strong presence around larger cities in metropolitan areas. Major segments of middle-status white-collar employees find themselves pressured financially to maintain what is viewed as a middle-class and suburban level of living. This is seen in widespread credit abuse and second mortgages on houses purchased on installments. People in manual occupations are very likely to be dependent on two incomes.

Poverty is also a stronger presence in the suburban portions of metropolitan regions. The federal standard for the measurement of poverty is based on the ability of an individual or family to purchase food. Under the official methods of determining poverty levels, around one person in eight in the United States is in poverty. One-third of the people classified as poor under that standard live in a suburban location.

RESIDENTIAL PATTERNS OF MINORITY GROUPS IN METROPOLITAN AREAS

Impressions from the middle to the third quarter of the twentieth century linger in mass media and public imagery of the suburbs. Some of these stereotypical perceptions of suburbs as dwelling places for a white population have their source in the development of the early
suburbs around large cities in the late nineteenth and early twentieth centuries. As with much stereotyped imagery, they have some basis, historically, in fact. Also, at present some of the oldest and most established traditional incorporated suburbs in outlying areas of the largest North American cities exemplify what sociologists refer to as “suburban persistence,” meaning that they retain a significant degree of their original exclusiveness and Anglo-American characteristics.

In looking at metropolitan areas nationally, a different picture emerges. Almost 40 percent of black Americans live in a suburban location, and a growing proportion of this population continues to move to the suburbs. Half of the people from a Latino background are suburban dwellers. For the last two decades or so, Latino people have accounted for around one-quarter of all suburban growth in the United States. Finally, although a small proportion of the total population, 55 percent of all Asian Americans live in suburbs, often in suburbs that are predominantly Asian but contain a significant proportion of Anglo-American residents.

METROPOLITAN REGIONS, THE SUBURBS, AND CHANGES IN POLITICAL BEHAVIOR

The deconcentration of population around large urban areas in the United States is associated with changes in politics, political alignments, and election outcomes in public life. First is the large number of political jurisdictions in the multicentered urban region. This has many implications, but the most direct impact is on the region and its frequent inability to regulate urban sprawl and its connected problems of leapfrog growth, traffic congestion, and pollution as well as maintaining clean water resources. There is also a growth in the number of local public officials, and as regional-level problems develop, these officials are often unable to operate in a coordinated manner to resolve them and ameliorate the social problems that arise from the organizational features of the metropolitan region. At the national level, the changes reviewed above are reflected in new areas of influence with altered political alignments. Central-city areas have declined in political influence, and an urban, union-influenced vote has determined fewer outcomes than in past decades. The suburban vote is not easy to characterize as it is not nearly as uniformly conservative as it was in past generations. Recent elections have seen a shift toward independent voters in the suburbs, who are issues-oriented and often concerned about lifestyle, with weakened ties to traditional social-class-based political involvement.

In conclusion, central cities are no longer the dominant locations in political decisions and economic activity in metropolitan regions. The newer territorial organization is multicentered, with edge cities and specialized nodes developing along major interstate highways and with services used by a more affluent suburban population. Ethnic variation is commonplace in suburban areas, as is manufacturing activity with suburban commuting working-class populations. Shopping malls are the predominant medium for retail business, and most jobs are in the services sector. Typical commuting occurs from one suburb to another. The longer term effect on politics is not clear, but regional problems are far from experiencing resolution at the local, regional, or national level.

REGRESSION

Regression is a broad class of statistical models that is the foundation of data analysis and inference in the social sciences. Moreover, many contemporary statistical methods derive from the linear regression model. At its heart, regression describes systematic relationships between one or more predictor variables with (typically) one outcome. The flexibility of regression and its many extensions make it the primary statistical tool that social scientists use to model their substantive hypotheses with empirical data.

HISTORY AND DEFINITION

The original application of regression was Sir Francis Galton’s study of the heights of parents and children in the late 1800s. Galton noted that tall parents tended to have somewhat shorter children, and vice versa. He described the relationship between parents’ and children’s heights using a type of regression line and termed the phenomenon regression to mediocrity. Thus, the term regression described a specific finding (i.e., relationship between parents’ and children’s heights) but quickly became attached to the statistical method.

The foundation of regression is the regression equation; for Galton’s study of height, the equation might be: Child = β₀ + β₁ (Parent) + εᵢ. Each family provides values for child’s height (i.e., Childᵢ) and parent’s height (i.e., Parentᵢ). The simple regression equation above is identical with the mathematical equation for a straight line, often expressed as y = mx + b. The two regression coefficients (i.e., β₀ and β₁) represent the y-intercept and slope. The y-intercept estimates the average value of children’s height when parent’s height equals 0, and the slope coefficient estimates the increase in average children’s height for a 1-inch increase in parent’s height, assuming height is measured in inches. The intercept and slope define the regression line, which describes a linear relationship between children’s and parents’ heights. Most data points (i.e., child and parent height pairs) will not lie directly on the simple regression line; the scatter of the data points around the regression line is captured by the residual error term εᵢ, which is the vertical displacement of each datum point from the regression line.

The regression line describes the conditional mean of the outcome at specific values of the predictor. As such, it is a summary of the relationship between the two variables, which leads directly to a definition of regression: “[to understand] as far as possible with the available data how the conditional distribution of the response … varies across subpopulations determined by the possible values of the predictor or predictors” (Cook and Weisberg 1999, p. 27). This definition makes no reference to estimation (i.e., how are the regression coefficients determined?) or statistical inference (i.e., how well do the sample coefficients reflect the population from which they were selected?). Historically, regression has used least-squares estimation (i.e., coefficient values are found that minimize the squared errors εᵢ) and frequentist inference (i.e., variability of sample regression coefficients are examined within theoretical sampling distributions and summarized by p-values or confidence intervals). Although least-squares regression estimates p-values based on frequentist inference are the most common default settings within statistical packages, they are not the only methods of estimation and inference available, nor are they inherently aspects of regression.

EXTENSIONS OF THE BASIC REGRESSION MODEL

If regression only summarized associations between two continuous variables, it would be a very limited tool for social scientists. However, regression has been extended in numerous ways. An initial and important expansion of the model allowed for multiple predictors and multiple types of predictors, including continuous, binary, and categorical. With the inclusion of categorical predictors, statisticians noted that analysis of variance models with a single error term and similar models are special cases of regression, and the two methods (i.e., regression and analysis of variance) are seen as different facets of a general linear model.

A second important expansion of regression allowed for different types of outcome variables such as binary, ordinal, nominal, and count variables. The basic linear regression model uses the normal distribution as its probability model. The generalized linear model, which includes non-normal outcomes, increases the flexibility of regression by allowing different probability models (e.g., binomial distribution for binary outcomes and Poisson distribution for count outcomes), and predictors are connected to the outcome through a link function (e.g., logit transformation for binary outcomes and natural logarithm for count outcomes).

Beyond the general and generalized linear models, numerous other extensions have been made to the basic regression model that allow for greater complexity, including multivariate outcomes, path models that allow for multiple predictors and outcomes with complex associations, structural equation models that nest measurement models for latent constructs within path models, multilevel models that allow for correlated data due to nested designs (e.g., students within classrooms), and nonlinear regression models that use regression to fit complex mathematical models in which the coefficients are not additively related to the outcome. Although each of the preceding methods has unique qualities, they all derive from the basic linear regression model.
REGRESSION AS A TOOL IN SOCIAL SCIENCE RESEARCH

Research is a marriage of three components: Theory-driven research questions dictate the study design, which in turn dictates the statistical methods. Thus, statistical methods map the research questions onto the empirical data, and the statistical results yield answers to those questions in a well-designed study. Within the context of scientific inquiry, regression is primarily an applied tool for theory testing with empirical data. This symbiosis between theoretical models and statistical models has been the driving force behind many of the advances and extensions of regression discussed above.

Although regression can be applied to either observational or experimental data, regression has played an especially important role in observational data. With observational data there is no randomization or intervention, and there may be a variety of potential causes and explanations for the phenomenon under study. Regression methods allow researchers to statistically control for additional variables that may influence the outcome. For example, in an observational study of infidelity that focuses on age as a predictor, it might be important to control for relationship satisfaction, as previous research has suggested it is related to both the likelihood of infidelity and age. Because regression coefficients in multiple regression models are estimated simultaneously, they control for the presence of the other predictors, often described as partialing out the effects of other predictors.

Regression can also play a practical role in conveying research results. Regression coefficients as well as regression summaries (e.g., percentage of the outcome variability explained by the predictors) quantitatively convey the importance of a regression model and consequently the underlying theoretical model. In addition, regression models are prediction equations (i.e., regression coefficients are scaling factors for predicting the outcome based on the predictors), and regression models can provide estimates of the outcome based on predictors, allowing the researcher to consider how the outcome varies across combinations of specific predictor values.

LIMITATIONS

Even though regression is an extremely flexible tool for social science research, it is not without limitations. Not all research questions are well described by regression models, particularly questions that do not specify outcome variables. As an example, cluster analysis is a statistical tool used to reveal whether there are coherent groups or clusters within data; because there is no outcome or target variable, regression is not appropriate. At the same time, because regression focuses on an outcome variable, users of regression may believe that fitting a regression model connotes causality (i.e., predictors cause the outcome). This is patently false, and outcomes in some analyses may be predictors in others. Proving causality requires much more than the use of regression.

Another criticism of regression focuses on its use for statistical inference. To provide valid inference (e.g., p-values or confidence intervals), the data must be a random sample from a population, or involve randomization to a treatment condition in experimental studies. Most samples in the social sciences are samples of convenience (e.g., undergraduate students taking introductory psychology). Of course, this is not a criticism of regression per se, but of study design and the limitations of statistical inference with nonrandom sampling. Limitations notwithstanding, regression and its extensions continue to be an incredibly useful tool for social scientists.

Regression Analysis

The term "regression" was initially conceptualized by Francis Galton (1822–1911) within the framework of inheritance characteristics of fathers and sons. In his famous 1886 paper, Galton examined the average regression relationship between the height of fathers and the height of their sons. A more formal treatment of multiple regression modeling and correlation was introduced in 1903 by Galton’s friend Karl Pearson (1857–1936). Regression analysis is the statistical methodology of estimating a relationship between a single dependent variable (Y) and a set of predictor (explanatory/independent) variables (X₁, X₂, ..., Xₖ) based on a theoretical or empirical concept. In some natural science or engineering applications, this relationship is exactly described, but in most social science applications, these relationships are not exact. These nonexact models are probabilistic in nature and capture only approximate features of the relationship. For example, an energy analyst may want to model how the demand for heating oil varies with the price of oil and the average daily temperature. The problem is that energy demand may be determined by other factors, and the nature of the relationship between energy demand and explanatory variables is unknown. Thus, only an approximate relation can be modeled.

The simplest relationship between Y and X is a linear regression model, which is typically written as,

\[ Y_i = \beta_0 + \beta_1 X_{1i} + \beta_2 X_{2i} + \ldots + \beta_k X_{ki} + U_i \]

where the index i represents the i-th observation and \( U_i \) is the random error term. The \( \beta \) coefficients measure the net effect of each explanatory variable on the dependent variable, and the random disturbance term captures the net effect of all the factors that affect Y except the influence of the predictor variables. In other words, \( U_i \) is the difference between the actual and mean value \( E(Y/X_i, i = 1, 2, ..., k) = \beta_1 + \beta_2 X_{1i} + \beta_3 X_{3i} + \ldots + \beta_k X_{ki} \) of the dependent variable. It is customary to assume that \( U_i \) is independently normally distributed with zero mean and constant variance (\( \sigma^2 \)). The parameters are estimated from a random sample of \( n(n > k) \) observations. The explanatory variables are assumed to be nonstochastic and uncorrelated with the error term. The meaning of the \( \beta \) coefficient varies with the functional form of the regression model. For example, if the variables are in linear form, the net effect represents the rate of change, and if the variables are in log form, the net effect represents elasticity, which can be interpreted as a percentage change in the dependent variable with respect to a 1 percent change in the independent variable.

The parameters \( \beta \)'s are estimated by minimizing the residual sum of squares \( \sum_{i=1}^{n} U_i^2 = \sum_{i=1}^{n} (Y_i - \beta_0 - \beta_1 X_{1i} - \beta_2 X_{2i} - \ldots - \beta_k X_{ki})^2 \), which is known as the ordinary least squares (OLS) method. The minimization problem results in \( k \) equations in \( k \) unknowns, which gives a unique estimate as long as the explanatory variables are not collinear. An unbiased estimate of \( \sigma^2 \) is obtained from the residual sum of squares. When the random error term satisfies the standard assumptions, the OLS method gives the best linear unbiased estimates (BLUE). The statistical significance of the coefficients is tested with the usual t-statistic \( t(= \beta / \text{s.e.}(\beta)) \), which follows a t-distribution with \( n - k \) degrees of freedom. In fact, some researchers use this t-statistic as a criterion in a stepwise process to add or delete variables from the preliminary model.

The fit of the regression equation is evaluated by the statistic \( R^2 \), which measures the extent of the variation in Y explained by the regression equation. The value of \( R^2 \) ranges from 0 to 1, where 0 means no fit and 1 means a perfect fit. The adjusted \( R^2 \) \( (R^2 = 1 - (1 - R^2)(n-1)/(n-k)) \), which compensates for \( n \) and \( k \), is more suitable than \( R^2 \) in comparing models with different subsets of explanatory variables. Sometimes researchers choose the model with the highest \( R^2 \), but the purpose of the regression analysis is to obtain the best model based on a theoretical concept or an empirically observed phenomena. Therefore, in formulating models, researchers should consider the logical, theoretical, and prior knowledge between the dependent and explanatory variables. Nevertheless, it is not unusual to get high \( R^2 \) with the signs of the coefficients inconsistent with prior knowledge or expectations. Note that \( R^2 \)'s of two different models are comparable only if the dependent variables and the number of observations are the same, because \( R^2 \) measures the fraction of the total variation in the dependent variable explained by the regression equation. In addition to \( R^2 \), there are other measures, such as Mallows’s Cₜ statistic and information criteria AIC (Akaiki) and BIC (Bayesian), to choose between different combinations of regressors. Francis Diebold (1998) showed that there is no obvious advantage between AIC or BIC, and they are routinely calculated in many statistical programs.

Regression models are often plagued with data problems, such as multicollinearity, heteroskedasticity, and autocorrelation, that violate standard OLS assumptions. Multicollinearity occurs when two or more (or a combination of) regressors are highly correlated. Multicollinearity is suspected when inconsistencies in the estimates, such as high \( R^2 \) and low t-values or high pairwise correlation among regressors, are observed. Remedial measures of multicollinearity include dropping a variable that causes multicollinearity, using a priori information to combine coefficients, pooling time series and cross-section data, adding new observations, transforming variables, and ridge or Stein-rule estimates. It is worthwhile to note that transforming variables and dropping variables may cause specification errors, and Stein-rule and ridge estimates produce biased and inefficient estimates.

138 INTERNATIONAL ENCYCLOPEDIA OF THE SOCIAL SCIENCES, 2ND EDITION
The assumption of constant variance of the error term is somewhat unreasonable in empirical research. For example, expenditure on food is steady for low-income households, while it varies substantially for high-income households. Furthermore, heteroskedasticity is more common in cross-sectional data (e.g., sample surveys) than in time series data, because in time series data, changes in all variables are in more or less the same magnitude. Plotting OLS residuals against the predicted Y values provides a visual picture of the heteroskedasticity problem. Formal tests for heteroskedasticity are based on regressing the OLS residuals on various functional forms of the regressors. Halbert White’s (1980) general procedure is widely used among practitioners in detecting and correcting heteroskedasticity. Often, regression models with variables observed over time conflict with the classical assumption of uncorrelated errors. For example, in modeling the impact of public expenditures on economic growth, the OLS model would not be appropriate because the level of public expenditures are correlated over time. OLS estimates of \( \beta \) in the presence of autocorrelated errors are unbiased, but there is a tendency for \( \sigma^2 \) to be underestimated, leading to an overestimated \( R^2 \) and invalid t- and F-tests. First-order autocorrelation is detected by the Durbin-Watson test and is corrected by estimating difference equations or by the Cochrane-Orcutt iterative procedure.

**SPECIFICATION ERRORS**

The OLS method gives the best linear unbiased estimates contingent upon the standard assumptions of the model and the sample data. Any errors in the model and the data may produce misleading results. For example, the true model may have variables in log form, but the estimated model is linear. Even though in social sciences, the true nature of the model is almost always unknown, the researchers’ understanding of the variables and the topic may help to formulate a reasonable functional form for the model. In a situation where the functional form is unknown, possible choices include transforming variables into log form, polynomial regression, a translog model, and Box-Cox transformation. Parameters of the Box-Cox model are estimated by the maximum likelihood method because the variable transformation and the parameter estimation of the model are inseparable.

Specification errors also occur either when relevant explanatory variables are missing from the model or when irrelevant variables are added to the model. For example, let the true regression model be \( Y = \beta_1 + \beta_2 X_2 + \beta_3 X_3 + U \) and the estimated model be \( Y = \hat{\beta}_1 + \hat{\beta}_2 X_2 + \hat{\beta}_3 X_3 + U \). If the omitted variable \( X_3 \) is correlated with the included variable \( X_2 \), then the estimates of \( \beta_1 \) and \( \beta_2 \) are biased and inconsistent. The extent and the direction of the bias depends on the true parameter \( \beta_3 \) and the correlation between the variables \( X_2 \) and \( X_3 \). In addition, incorrect estimation of \( \sigma^2 \) may lead to misleading significance tests. Researchers do not commit these specification errors willingly; often the errors are due to unavailability of data or lack of understanding of the topic. Researchers sometimes include all conceivable variables without paying much attention to the underlying theoretical framework, which leads to unbiased but inefficient estimates, which is less serious than omitting a relevant variable.

Instead of dropping an unobserved variable, it is common practice to use proxy variables. For example, most researchers use general aptitude test scores as proxies for individual abilities. When a proxy variable is substituted for a dependent variable, OLS gives unbiased estimates of the coefficients with a larger variance than in the model with no measurement error. However, when an independent variable is measured with an error, OLS gives biased and inconsistent estimates of the parameters. In general, there is no satisfactory way to handle measurement error problems. A real question that arises is whether to omit a variable altogether or instead use a proxy variable. B. T. McCallum (1972) and Michael Wickens (1972) showed that omitting a variable is more severe than using a proxy variable, even if the proxy variable is a poor one.

**CATEGORICAL VARIABLES**

In regression analysis, researchers frequently encounter qualitative variables, especially in survey data. A person’s decision to join a labor union or a homemaker’s decision to join the workforce are examples of dichotomous dependent variables. Dichotomous variables also appear in models due to nonobservance of the variable. In general, a dichotomous variable model can be defined as,

\[
Y^* = X_\beta + U,
\]

where \( X_\beta = \beta_1 X_1 + \beta_2 X_2 \) and \( Y \) is an unobservable variable. An observable binary outcome variable \( Y \) is defined as,

\[
Y = \begin{cases} 
1 & \text{if } Y^* \text{ exceeds zero and} \\
0 & \text{if otherwise.}
\end{cases}
\]

Substituting \( Y \) for \( Y^* \), and estimating the model by OLS is unsuitable primarily because \( X_\beta \) represents the probability \( Y = 1 \) and it could lie outside the range 0 to 1. In the probit and logit formulations of the above model, the probability that \( Y \) is equal to 1 is defined as a probability distribution function,

\[
Pr(Y = 1) = Pr(Y^* > 0) = Pr(U > X_\beta) = 1 - F(-X_\beta)
\]

where \( F \) is the cumulative distribution function of \( U \). The choice of the distribution function \( F \) translates the regres-
Regression Analysis

... tion function $X'\beta$ into a number between 0 and 1. Parameters of the model are estimated by maximizing the likelihood function,

$$L(\beta, b_i) = \prod_{i} I_{Y_i = F(-X_i\beta)} I_{Y_i = 1 - F(-X_i\beta)}$$

Choosing the normal probability distribution for $F$ gives the logit model where $\Phi(.)$ is the cumulative normal distribution function. Many statistical packages have standard routines to estimate both probit and logit models. In the probit model, the $\beta$ parameters and $\sigma$ appear as a ratio, and therefore cannot be estimated separately. Hence, in the probit model, $\sigma$ is set to 1 without any loss of generality. The cumulative distributions of logit and normal are close to each other, except in the tails, and therefore, the estimates from both models will not be much different from each other. Since the variance of the normal distribution is set to one, and the logistic distribution has a variance of $\pi^2/3$, it is necessary to divide the logit estimates by $\pi^2/3$ to make the estimates comparable. In practical applications, it is useful to compare the effect of each explanatory variable on the probability. A change in probabilities in the probit and logit models for a unit change in the $k$-th variable are given by $\pi(X_k\beta)/(1 + \exp(X_k\beta))$ and $\exp(X_k\beta)/(1 + \exp(X_k\beta))^2$, respectively, where $\varphi(.)$ is the standard normal probability density function.

In the multivariate probit models, dichotomous variables are jointly distributed with appropriate multivariate distributions. Likelihood functions are based on the possible combinations of the binary choice variable ($Y$) values. A practical difficulty in multivariate models is the presence of multiple integrals in the likelihood function. Some authors have proposed methods for simulating the multivariate probabilities; details were published in the November 1994 issue of the *Review of Economics and Statistics*. This problem of multiple integration does not arise in the multinomial logit model because the cumulative logistic distribution has a closed form.

TOBIT MODEL

The Tobit model can be considered as an extension of the probit and logit models where the dependent variable $Y_i^*$ is observed in the positive range and is unobserved or unavailable in the negative range. Consider the model described in equation (2), where

$$Y_i = \begin{cases} Y_i^* & \text{if } Y_i^* > 0 \text{ and } \\ 0 & \text{if } Y_i^* \leq 0. \end{cases}$$

This a censored regression model where $Y$ observations below zero are censored or not available, but the $X$ observations are available. On the other hand, in the truncated regression model, both $Y$ and $X$ observations are unavailable for $Y$ values below zero. Estimation of parameters are carried out by the maximum likelihood method, where the likelihood function of the model is based on $P(Y > 0)$ and $P(Y \leq 0)$. When $U_i$ is normally distributed, the likelihood function is given by,

$$L = \prod_{i: \gamma_i < 0} [1 - \Phi(X_i\beta)] \prod_{i: \gamma_i > 0} \frac{1}{\sigma \sqrt{2\pi}} \exp \left(-\frac{(Y_i - X_i\beta)^2}{2\sigma^2} \right)$$

Unlike the probit model, where $\sigma$ is arbitrarily set to 1, the Tobit model estimates the parameters. In the probit model, only the effect on the probabilities for changes in $X$ values are meaningful to a practitioner. However, in the Tobit model, a practitioner may be interested in how the predicted values of $Y_i^*$ change due to a unit change in one $X$ variable in three possible scenarios of the model, linear functional form, unconditional mean and conditional mean (i.e., $E(Y_i | X) = X\beta, E(Y_i) \text{ and } E(Y_i | Y_i > 0)$). The impacts of the variable $X_i$ on the above three expressions are given by the $\beta_i, \varphi(Z), \beta_i [1 - Z \varphi(Z)/\Phi(Z) - \varphi(Z)/\Phi(Z)^2]$, respectively, where $Z = X_i\beta/\sigma$, and $\varphi()$ and $\Phi()$ are standard normal density and distribution functions. An extension of the Tobit model with the presence of heteroskedasticity has been proposed by James Powell (1984).

CAUSALITY BETWEEN TIME SERIES VARIABLES

The concept of causality in time series variables was introduced by Norbert Wiener (1956) and Clive W. J. Granger (1969), and refers to the predictability of one variable $X_t$ from its past behavior, another variable $Y_t$, and a set of auxiliary variables $Z_t$. In other words, causality refers to a certain type of statistical feedback between the variables. Some variables have a tendency to move together—for example, average household income and level of education. The question is: Does improvement in education level cause the income to increase or vice versa? It is also worthwhile to note that even with a strong statistical relation between variables, causation between the variables may not exist. The idea of causation must come from a plausible theory rather than from statistical methodology. Causality can be tested by regressing each variable on its own and other variables’ lagged values.

A closely related concept in time series variables, as well as in cross-sectional data to a lesser degree, is simultaneity, where the behavior of $g$ ($g > 1$) stochastic variables are characterized by $g$ structural regression equations. Some of the regressors of these regression equations contain stochastic variables that are directly correlated with...
the random error term. OLS estimates of such a model produce biased estimates, and the extent of the bias is called *simultaneity bias*. The implications of simultaneity were recognized long before the estimation methods were devised. Within the regression analysis context, the identification problem has another dimension—that is, whether the difficulty in determining a variable is truly random or not. Moreover, a more serious fundamental question that arises is whether the parameters of a model are estimable.

**BIBLIOGRAPHY**

---

**REGRESSION TOWARDS THE MEAN**

Regression towards the mean is a fundamental yet at first sight puzzling statistical phenomenon occurring between data from two variables, and it is a natural and inherent consequence of correlation being generally imperfect.

The effect of regression towards the mean was recognized in the late nineteenth century by Francis Galton (1822–1911) when investigating the relationship of the heights of parents and their adult children (see Bland and Altman 1994, Stigler 1986). Such height data are positively correlated; tall parents tend to produce tall adult children.

The diagram shows an ellipse that represents a cloud of correlated data points. The X and Y values are assumed for simplicity here to have equal mean and equal standard deviation. The X and Y values for Galton would be parent’s height and adult offspring’s height, but they could be any correlated variables, for example a measure of crime...
on some scale, for a sample of areas at one time, \( X \), and at a later time, \( Y \). The tilt of the ellipse shows that high values earlier are associated with high values later and vice versa; that is, positive correlation exists. Also on the diagram is the line of equality going diagonally bottom left to top right along the major axis of the ellipse. (Equality means that its slope = 1). Any point below this line indicates that the value of \( Y \) is smaller than that of \( X \), whereas a point above indicates that it is greater. If correlation was perfect, the ellipse would narrow and become identical with the line of equality.

Also on the diagram is a line of shallower slope that gives the mean of \( Y \) for a given \( X \). This is the conditional mean of \( Y \). One can see that the conditional mean of \( Y \) given \( X \) is not the line of equality, because taking a vertical slice through the ellipse shows that the bulk of the distribution lies above the line of equality for an \( X \)-value below the mean of \( X \), whereas it is below the line for an \( X \)-value above the mean of \( X \). In fact, the line of the conditional mean for the situation described, that is, with standard deviations of \( X \) and \( Y \) equal, has a slope equal to the (Pearson) correlation coefficient. Therefore, the expected \( Y \)-value for a given \( X \)-value, in other words the conditional mean, is above the line of equality for \( X \) below the mean of \( X \), and below the line of equality for \( X \) above its mean. Therefore, there is a tendency for values to be closer to the overall \( Y \)-mean, the effect being greater the weaker the correlation is.

This is precisely what Galton found: that the heights of adult children tended to be closer to the mean of the population than their parents’ heights were; that is, they regressed towards the mean. Note that this does not make every one the same height in the end—the distribution can remain stable generation after generation.

A similar situation applies in a more general case than that described when neither the means nor the standard deviations of \( X \) and \( Y \) variables are equal to each other, such as when successive generations are getting taller on average and becoming more variable in absolute terms, that is, in centimeters. In a more general case such as this the elliptical cloud of data points will be shifted up and will have greater vertical extension due to the greater standard deviation of the \( Y \) variable. The major axis of the elliptical cloud will no longer be the line of equality, but will still represent the line that the ellipse shrinks towards as the correlation becomes perfect. As in the earlier case, the line of conditional mean is still at a shallower slope than the major axis, and so the same effect occurs, that there is regression towards the mean such that the expected \( Y \)-value will be fewer \( Y \)-standard deviations from the \( Y \)-mean than the \( X \)-value is \( X \)-standard deviations from the \( X \)-mean. In fact, for an \( X \)-value \( Z_x \) standard deviations from the \( X \)-mean the expected \( Y \)-value will be “(1-correlation coefficient) multiplied by \( Z_y \)” standard deviations in \( Y \) from the major axis line, and equivalently only “correlation coefficient multiplied by \( Z_x \)” standard deviations in \( Y \) from the \( Y \)-mean. So, for example, if the \( X \)-value is 1.5 standard deviations above its mean and the correlation coefficient between \( X \) and \( Y \) is 0.2, then the expected \( Y \)-value is only 0.3 standard deviations above its mean, that is, 1.2 below the original number of standard deviations.

The statistical method of regression owes its name to the discovery by Galton of this effect. Indeed, the regression line is simply the line of the conditional mean, exactly as discussed above. It is a surprise to some that the regression line does not run along the major axis of the cloud of data points. The equation for the line of conditional mean can be determined mathematically (see, for example, Freund 2004, which treats the more general case).

A consequence of the effect of regression towards the mean is if an intervention is applied to a group with high values before, for example a bad state before, and the control is another with lower values, a better state before, one is likely to find that the intervention appears to work even if it really has no superior effect. This is because the expectation is that the higher measurements will become lower. It is therefore vital that comparison is made like with like.

While it is possible to envisage situations that are more complex than those described above, so that the conditional mean is consequently no longer a simple straight line, one should never assume that the effect described is nonexistent.

Regulation

Regulation involves attempts by the government to monitor and correct any disorders in the workings of free markets. Formally, economic regulation refers to all types of taxes and subsidies as well as to governmental controls over prices, market entry, and other aspects of economic activity. Some regulation might directly impose monetary costs (e.g., taxes or fines on noncompliers), while other types of regulation might impose costs indirectly by mandating standards that might be costly to adhere to. Examples of regulation include limits on emissions from vehicles, fire-retardant materials used in children’s bedding, airline safety standards, smoking bans, food safety, and consumer protection laws.

While the extent of government intervention in economic activity remains a matter of heated debate, few individuals would argue for a complete absence of regulation. Two widely accepted issues deserving of regulation might be related to a country’s monetary system (smooth working of the banking system and the money supply) and national defense. These attempts might be focused on both buyers and sellers, or might be directed at one of the parties. Banking laws are examples of laws that affect both buyers and sellers, while regulations by the Occupational Safety and Health Administration (OSHA) can be viewed as aimed directly at sellers. The disorders or imperfections that regulation seeks to rectify might be related to prices (too high prices), quantity or service (not all customers being served), reliability (failure to adhere to schedules), and fairness, among other issues. In practice, common instances of regulation include promotion of competition, safeguarding the interests of buyers or sellers (or both), protecting the environment, and defending national interests. For instance, the Clayton Act and the Sherman Act are two primary laws in the United States that deal with provision of fair market competition.

HISTORICAL PERSPECTIVE

Historically speaking, regulations have changed over time with new technologies, new concerns, and new revelations (e.g., harmful environmental effects of certain known substances). Sometimes, however, certain unexpected events bring about a flurry of regulations (or deregulations) in a rather short period of time. Examples of such events include the Great Depression, the 1973 oil embargo, and certain natural calamities. The Great Depression prompted governments to better regulate their economies so they could prevent wide and sudden variations in the unemployment and inflation rates. In the United States, the Federal Reserve System, which governs the money supply and oversees the banking system, was a direct offshoot of the Great Depression. The oil embargo led to various regulations regarding oil conservation including provisions for minimum fuel efficiency on automobiles. Further, natural disasters such as hurricanes and earthquakes can lead to tougher building codes in vulnerable areas.

Governments generally set up regulatory agencies to impose and monitor regulations. These agencies usually have semi-autonomous status to keep them relatively free of political pressures, although in a number of instances the regulated agencies end up enforcing the regulations passed by the executive branch. These agencies might be national (Federal Communications Commission), or they may be sub-national (Illinois Commerce Commission). In some instances, cross-national organizations such as the World Bank and United Nations impose codes of conduct across nations. However, such regulations generally are difficult to enforce and are usually less effective.

THEORETICAL UNDERPINNINGS

The theoretical underpinnings of regulation may be understood in the context of the three widely cited theories of regulation: (1) public interest theory; (2) capture theory; and (3) economic theory of regulation. According to the public interest theory, regulation is supplied or enacted by governments to correct inefficient and/or unfair market practices or outcomes. However, this theory implicitly assumes that regulators have the capacity and the willpower to determine what is fair and efficient. Since the late twentieth century, the public interest theory has been somewhat revised to recognize that regulatory agencies themselves might be inefficient. It is also unclear from this theory how public interest matters take the form of legislation. The capture theory of regulation can be seen as drawing from both economics and political science. According to this theory, regulatory agencies over time tend to be dominated or influenced by the industries they...
Regulate. In other words, the integrity of the regulatory agencies tends to be compromised by their clientele. This theory, however, ignores special interest groups other than the regulated industries (e.g., consumers). The economic theory of regulation is primarily due to the work of the scholar George Stigler. This theory suggests that the economic laws of demand and supply can be employed to understand regulation. Alternately stated, the optimal amount of regulation would balance the demand and supply of government intervention. The demanders of regulation may be viewed as special interest groups (consumers) or parties being harmed by the current state of affairs (businesses unable to compete in protected markets). The suppliers of regulation are the regulatory agencies. This theory also recognizes that in the real world enactment of rules and regulations is not based purely on economic considerations. Rather, they are enacted in a political-economic context. The use of the laws of demand and supply enables efficiency in the provision of regulation. However, the economic theory of regulation has not been refined to the point where it enables us to predict specific industries in which regulation will be found.

IMPLEMENTATION AND BENEFITS
In imposing various types of regulation, regulators should be mindful of equity or fairness aspects on the one hand and efficiency or waste considerations on the other hand. Generally, there is a tradeoff between the two criteria. For instance, some regulatory intervention that is relatively equitable (e.g., minimum wage laws providing a “fair” wage to unskilled or less-skilled workers) is usually not efficient (i.e., minimum wage laws do not allow the markets to work efficiently and impose undue hardships on some businesses). Thus, regulators have to weigh relative pros and cons of intervention and impose the socially optimal level of regulation. The socially optimal level would generally be less than total regulation (e.g., there should be a socially desirable level of pollution; getting rid of all pollution would impose undue costs on the society in terms of sacrifices to be made, such as no electricity generated via nuclear or thermal power plants and no polluting vehicles).

The main benefit of regulation is that it corrects shortcomings in the workings of markets. Some benefits of regulation, however, might be diffused over time, while the costs might be upfront. In such cases, it becomes difficult for regulators to convince the affected parties of the desirability of regulation. An example of this may be environmental regulation. Regulations mandating the cleanup of toxic waste dumps impose costs up front but their benefits in terms of improvement in the environment and related health benefits would only be realized over time.

The costs of regulation include the costs of compliance and the costs of monitoring. Sometimes the monitoring costs can turn out to be very high with the result that in certain instances products might either not be regulated or not be regulated effectively. Other times there are unexpected consequences of regulation when markets are connected or are interdependent. For instance, tougher regulation ensuring the purity of the milk supply would affect the milk industry directly, but also related industries that make use of dairy products (restaurants, cheese, coffee, and ice cream, for example).

Price regulation might impose direct price controls on products (price cap regulation), or it might control prices indirectly (via rate of return regulation where regulated firms are free to set prices, provided they do not earn above a specified rate of return on capital). Price cap regulation can affect the regulated firm’s investments in research and development, while it has been shown that the rate of return regulation leads to overcapitalization (i.e., regulated firms would use more capital than they would in the absence of such regulation). Thus, one type of regulation does not seem suitable for all cases.

Sometimes regulation is uncertain and not all types of intervention are predictable. Such uncertainty might plague both suppliers of regulation (i.e., government) and the parties affected by regulation. Governments might not know a priori whether they would have to regulate a new technology (new supersonic airplane) because of some future undesirable side effects (new airplane too noisy for residential areas). The public is uncertain whether and when current or future products might face additional regulations. A case in point is the impending threat of restrictions on cell phone usage while driving.

In practice, even after regulators have determined that certain products or industries need to be regulated, there is generally a time delay (called a regulatory lag) between the realization of the need for intervention, the enactment of relevant laws and their implementation. This reduces the effectiveness of regulatory intervention as it affords the affected parties time to find ways to circumvent the regulations. In certain cases, the regulatory lag might be long enough to make rules unnecessary when they are finally put into place.

In conclusion, regulation seems essential in many instances. One could differ in one’s perceptions about the scope of regulation, but its desirability in many instances seems real. Over time government intervention needs to be dynamic to be efficient and effective. Certain industries might not need regulations over time, while new regulatory instruments might have to be developed in other instances, such as in the regulation of the Internet.

Reincarnation

Reincarnation is the cultural belief that human beings can be born and reborn in endless cycles of births and rebirths. Forms of reincarnation are found in a wide range of human societies, ranging from small scale or “tribal” groups to the ancient Greeks and most conspicuously, those religions that developed in India during and after 6 BCE, if not earlier. Nevertheless, there has been a surprising lack of ethnographic documentation of the cross-cultural spread of these religions. The reasons are many: Perhaps most significant was the impact of Christian missions generally hostile to indigenous religions, especially reincarnation theories that were declared “anathema” by the Church in 553 CE.

Until recent times ethnographers were unfamiliar with such doctrines and tended to subsume them under the better known class of “ancestor cults,” easy enough to do because reincarnation is often associated with the world of ancestors. Additionally, there was the widespread prejudice that reincarnation is uniquely associated with Indic religions like that of Buddhism and Hinduism, tending scholars to neglect its presence elsewhere. The historical evidence is clear that reincarnation doctrines known as metempsychosis, metacosmesis, or metemnematosis existed in ancient Greece even prior to the Buddha in the cosmology of Pythagoras. These doctrines continued outside of the dominant or mainline Greek traditions of cosmology between 7 BCE to about 3 CE through such figures as Empedocles, Pindar, Plato and the neo-Platonic traditions, especially Plotinus. Greek reincarnation doctrines influenced some Middle Eastern societies, most notably the Druze of Israel and Lebanon from around 1017 CE; the Shi’ite Nusayriyah of Western Syria belonging to the Ismā‘illī tradition around the same time; and the Alevis of Central Turkey, perhaps during the same time period although no clear historical evidence is available. All these societies had reincarnation theories that for the most part posited immediate reincarnation after death followed by rebirth in the larger religious community, if not a specific social group or clan.

Studies by ethnographers found that the presence of reincarnation doctrines among Northwest Coast Indians was the basis of the Indians’ eschatological and cosmic beliefs. These studies culminated in a 1994 pioneer work, Amerindian Rebirth: Reincarnation Beliefs among North American Indians and Inuit, which described a wide range of Amerindian groups believing in reincarnation. For Melanesia, the only detailed study is the classic work of anthropologist Bronislaw Malinowski (1884–1942). Malinowski documented in great detail the reincarnation theories of the Trobriand Islanders, most notably in his 1916 essay “Baloma: the Spirits of the Dead in the Trobriand Islands,” based on his fieldwork in New Guinea during World War I. A similar ethnographic lacuna exists for West Africa where scattered references indicate that reincarnation theories were widely prevalent before colonial contact. Fortunately, there are detailed ethnographic accounts for at least one large group, the Ibo of southeastern Nigeria, now highly Christianized but still retaining some of their traditional reincarnation beliefs. What the cross-cultural evidence reveals is that reincarnation doctrines are found in various parts of the world, many of whom were unaffected by Indic civilization.

In order to bring some order into widely dispersed reincarnation doctrines it is necessary to deal with their simplest manifestation among small-scale societies, and then the more complex Greek and Indic representatives. Propitiation of ancestors (“ancestor cults”) is a widespread form of religious life. After death, the spirit goes into a realm of the ancestors and ancestral spirits continue to interact with living persons, who in turn have to propitiate them. Only one structural feature is required for an ancestor cult to develop into a reincarnation doctrine. The spirit at death goes into the world of the ancestors and then, after a temporary stay in that realm, returns to the human world by being reborn among former kin. Then, after death, the spirit goes back to the ancestral world and the rebirth cycle continues. More complex systems are constructed upon this “elementary form” of a reincarnation doctrine.
Among small-scale societies there are two trajectories of rebirth: The Northwest Coast Indians and the Inuit share a widespread circumpolar complex (spreading into Central Asia) in affirming that after death one could be reborn as an animal. In West Africa and Melanesia one cannot be reborn except as a human being. When there is a belief in rebirth as an animal or when humans and animals have their own reincarnation cycles there develops a concomitant respect for animal life. Thus, while killing animals is necessary for existence, the Inuit hunter thanks the animal for its sacrificial gift and implores it to return to another rebirth, human or animal. Within the two broad complexes of being reborn as animal or human, there is considerable variation as to whether cross-sex reincarnation is possible or not.

The striking feature of reincarnation in small-scale societies is the absence of other-worldly rewards and punishments imposed on the departing soul at death, even though such societies have highly developed secular moral codes. Once the appropriate funeral rites have been performed, anyone can enter the temporary world of ancestors. By contrast, owing to Indian and Greek philosophical preoccupation with social morality and ethics, the entry into the other world is conditional on the good and bad done in this world. Thus, in Indian thought there developed the doctrine of “karma,” the idea that the good and bad humans do on earth will result in punishments or rewards in the other world, followed by similar rewards and punishments in the next reincarnation. By contrast, the Greek tradition does not have this uniformity although considerable emphasis is placed on other-world compensations rather than rewards in the next rebirth.

Greek reincarnation can be illustrated with an example from Plato in the final chapter of The Republic. Plato mentions the case of a warrior named Er whose spirit escaped after ten days while his hitherto undecomposed corpse was being cremated. Er then went on a long underground journey followed by a sojourn in a strange place where he confronted judges sitting beside two chasms. These judges order the righteous to take a right road of the heavenly chasms whereas the bad must take the left that went downward into places of punishment. Er was instructed to watch and remember the proceedings so that he could relay his experiences to fellow mortals when he returned to Earth. Er mentions specific punishments and rewards offered to people right then and there by the judges, the bad undergoing cruel but just punishment and the good enjoying the rewards of heaven.

Having expiated their past in this manner, people are now free beings who will eventually assemble in a meadow awaiting their rebirth in the human world. One of the Fates, the goddess Lachesis, gives the people a choice of “packages” containing their future life projections on Earth. Unhappily, people do not choose wisely. Enticed by power and wealth they pick the wrong life choices, often replicating the habits of their former lives on Earth. They come back to Lachesis who allocates each a guardian spirit; the other Fates seal these compacts making them irreversible. People then come to a land of dreadful thirst and reach Lethe, the river of forgetfulness. All drink the waters of Lethe except Er, who must remember to tell his tale to mortals when his spirit eventually returns to his corpse and revives it. The Platonic myth culminates in people going to sleep but when midnight comes there is an earthquake and thunder. Suddenly, the people are all swept up and away like shooting stars, here and there, propelled to another rebirth in the human world.

REINFORCEMENT THEORIES

For more than a century, the term reinforcement has referred to the emergence of a reliable, learned change in behavior produced when a response or stimulus is differentially followed by a rewarding or punishing event (a reinforcer). Early examples of instrumental reinforcement included: Edward Lee Thorndike’s (1874–1949) experiments with cats learning to escape (what he called) a puzzle box by manipulating a release mechanism for the door,
B. F. Skinner's (1904–1990) training of rats to press a lever for food, and the work of Willard Stanton Small (1870–1943) and Edward Chace Tolman (1886–1959) showing that rats could learn a maze path with, or without, food in the goal box. The dominant example of early Pavlovian reinforcement—from the work of the Russian physiologist Ivan Petrovich Pavlov (1849–1936)—showed that a dog could be conditioned to salivate to a signal predicting the imminent arrival of either meat powder or a weak acid solution in its mouth.

**THEORY WARS**

Each of the above examples provided an answer to a critical conceptual and practical question, “What conditions must be added to the simple repetition of a stimulus and/or a response to produce learning?” However, each answer also left notable theoretical questions unresolved. As a result, more than half of the twentieth century was spent on attempts to develop a general theory of learning. These theories differed in: (1) how learning was represented (for example, as stimulus-response or stimulus-stimulus associations, as cognitive maps, memories, or transmitted information; (2) the necessary and sufficient qualities of a reinforcer (for example, a drive reducer vs. a drive inducer); and (3) the necessary temporal and spatial relations between the response and/or stimulus and the reinforcer (for example, contiguity vs. contingency). For additional differences see the analyses in William K. Estes’s *Modern Learning Theory: A Critical Analysis of Five Examples* (1954) of Thorndike’s concept of the strengthening of neural connections, Edwin Ray Guthrie’s (1886–1959) emphasis on temporal contiguity and repetition, Tolman’s cognitive maps and expectancies, and Clark L. Hull’s (1884–1952) multiple learning variables and performance equations relating them to each other and behavior.

The theory wars were both exciting and frustrating. Excitement came from the development of extensive frameworks like Hull’s hypothetico-deductive system, which was applied to behaviors ranging from approach-withdrawal reactions (Neal E. Miller, 1944), to curiosity (Harry Fowler, 1967), and personality and psychotherapy (John Dollard and Neal E. Miller, 1950). Difficulties arose from the inability of researchers to agree on critical tests to distinguish alternative theories and concepts, and from the continued failure of general theories to account for important empirical phenomena like partial reinforcement, and incentive contrast. For example, Abram Amsel (1922–2006; 1992) and E. J. Capaldi (1967) showed that relatively unpredictable reinforcers produced greater resistance to extinction than more frequent but predictable reinforcers. Similarly, Charles F. Flaherty (c. 1937–2004; 1966) showed that the effects of presenting two different reinforcers depended on their order. The absence of a satisfying general theoretical account of diverse phenomena led many researchers to abandon the search for a general theory and focus on the empirical effectiveness and applications of specific reinforcement procedures.

**EFFECTIVE REINFORCEMENT PROCEDURES AND APPLICATIONS**

Thorndike claimed that all organisms were susceptible to the effects of reinforcement. Skinner supported the empirical generality of this claim by showing how reinforcement could be used to readily control the laboratory behavior of rats and pigeons. Marian Brelan Bailey and Keller Breland, early students of Skinner, handily extended his reinforcement approach to the training of animals in shows and zoos by using “bridge stimuli” (secondary reinforcers). During his lengthy career, Skinner focused increasingly on the control of human behaviors by reinforcers, at first by using reinforcement schedules to produce human-like behaviors in pigeons, including “superstitions” and “assembly-line” response patterns. In a recent continuation of this kind of comparative approach, Brian Lau and Paul W. Glimcher used brain scanning to identify specific areas involved in the well-known operant behavior of matching response rates to reinforcer frequency in rhesus monkeys.

Skinner also added a specific human focus, emphasizing the potential effects of operant conditioning on everyday human behavior in his writing of a utopian novel, *Walden Two* (1948), followed by several books of essays: *Science and Human Behavior* (1953), *Beyond Freedom and Dignity* (1971), and *About Behaviorism* (1974). Further, Skinner helped develop specific reinforcement applications in the form of programmed learning in education, and token economies for treating the mentally ill and deficient. Many examples of such procedures are described in an extensive applied literature, e.g., the *Journal of Applied Behavior Analysis*, and in edited volumes (such as William O’Donohue’s *Learning and Behavior Therapy*, 1998; see also work of Leonard Krasner).

**MOTIVATIONAL AND OPTIMALITY MODELS OF REINFORCEMENT**

Reinforcers, in terms of their ability to produce learning and behavior, were first limited largely to incentives that reduced physiological imbalances of the body; but reinforcers also can be novel stimuli, social or sexual cues, or simply access to a higher probability response. For example, William Timberlake and James W. Allison showed that reinforcement depends on the use of operant schedules that restrict access to a response or reinforcer relative to its free (unconstrained) baseline level. William
Timberlake and Valerie Farmer-Dougan reviewed how such a general regulatory framework could be translated to applied settings, and James W. Allison showed the relevance of regulatory work-income trade-offs to economic models (see Behavioral Economics 1983). J. E. R. Staddon (see Adaptive Dynamics: The Theoretical Analysis of Behavior, 2001) linked operant behavior to general optimization models, and J. C. David (see MacKay in Information Theory, Inference, and Learning Algorithms, 2003) and other scientists used computer modeling to produce optimizing algorithms leading to adaptive learning in machines.

**PAVLOVIAN MODELS OF REINFORCEMENT**

Beginning with work on information processing and interaction among predictive cues in the 1960s, Pavlovian conditioning became an important focus of reinforcement research and theory. Psychologists Robert A. Rescorla and Allan R. Wagner modeled the interaction of cues in Pavlovian conditioning using a variant of a linear operator model in which stimuli predicting a reinforcer compete for its incremental strengthening effect. Their model appropriately predicts that when two predictive stimuli are trained together, the more salient stimulus typically overshadows learning about the less salient stimulus, and a stimulus learned first most often interferes with (blocks) learning about a stimulus added later (although both facilitation and configural learning can occur in similar circumstances).

Subsequent researchers, like Ralph Miller and Mark E. Bouton, added a role for context conditioning, especially in application-related phenomena like the reinstatement of extinguished fear. Similar models of reinforcement have focused either on aspects of the interaction of Pavlovian and instrumental contingencies (see Geoffrey Hall, 2002), or on the scalar effect on acquisition speed and performance of the length of the CS relative to the length of inter-reinforcer interval (see a summary by Russell M. Church, 2002). Finally, Modelers such as Nestor A. Schmajuk (1977) have turned to the use of multilayer connectionist models, based on error-correction algorithms, to simulate interactions among multiple predictive cues.

To complete the picture, current investigators interested in neurophysiological substrates of learning often use Pavlovian and Operant reinforcement procedures to clarify the effects of brain stimulation, lesions, drugs (see Shepherd Siegel), neural transmitters and trans-gene manipulations (see Louis D. Matzel). Finally, considerable progress has been made in deciphering the contribution of simple sensory, motor, and Pavlovian mechanisms to learning related to species typical behavior. See the admirable book by Thomas J. Carew, 2000, in which he includes accounts of the neurophysiological work by Richard W. Thompson (see also Thompson, 2005) on conditioning of the nictitating membrane in rabbits, and by Eric Kandel (see also Frank Krasne, 1985) on gill withdrawal in Aplysia (sea slugs).

**EVOLUTIONARY AND ECOLOGICAL APPROACHES TO REINFORCEMENT**

A final approach to reinforcement began with twentieth-century researchers interested in evolution and learning. For example, T. C. Schneirla and M. E. Bitterman examined similarities and differences among species in reinforcement learning (see accounts in Comparative Psychology: A Handbook edited by Gary Greenberg and Martin Haraway). More recent investigators have explored the extent to which phenomena of human cognition can be produced by selective reinforcement of the perceptual choices of nonhuman animals. See Edward A. Wasserman and Thomas R. Zentall’s edited book on categorization and short-term memory mechanisms in animals, and edited book of Cecilia M. Heyes and Bennet G. Galef focused on imitation and social learning (Social Learning in Animals: The Roots of Culture).

More ecologically oriented researchers like John Garcia, Alan Kamil, David Sherry, and Charles R. Gallistel have clarified how ecologically specialized perceptual-motor learning mechanisms evolved to meet requirements for survival (summarized in Sara J. Shettleworth, 1998 Cognition, Evolution, and Behavior).

The relevance of such mechanisms to all laboratory research was pointed out by William Timberlake (2002) in examples of how ecologically-based abilities of common laboratory species have affected the design and results of common laboratory apparatus and procedures. Finally, work on human information-processing abilities, like that of John Tooby and Leda Cosmides on causal reasoning, and Paul Rozin and Carol Nemeroff on contamination and disgust reactions to foodstuffs, apply a similar ecological and evolutionary logic in the study of humans.

In short, given the diversity of reinforcement phenomena, mechanisms, and results, it appears that further increases in the effectiveness and generality of Reinforcement Theories and Models will depend on considering the effects of evolutionary, functional, applied, and neurophysiological contexts, rather than depending solely on general learning principles and theories.

REJECTION/Acceptance

Whether people perceive that they are socially rejected or accepted plays a role in determining how individuals evaluate themselves and the world around them. People who generally feel accepted or included by important others may fare better emotionally and interpersonally than people who generally feel rejected or excluded. In fact,
research has demonstrated that people may possess a fundamental need to belong that closely ties their feelings of self-worth, or self-esteem, with their yearnings for social acceptance (Baumeister and Leary 1995). Because of the apparent pervasiveness of people’s quest for social inclusion, systematic investigation of experiences and consequences of social rejection has enjoyed considerable popularity. Social psychologists, for example, may be interested in examining how people’s perceptions of inclusion or exclusion during a given situation may influence their self-esteem. Clinical psychologists, on the other hand, may be more interested in investigating the long-term consequences of people’s perceptions of inclusion or exclusion (e.g., marital satisfaction).

One theory of self-esteem, sociometer theory, states that people’s self-esteem and mood may function as a gauge, much like a fuel gauge, alerting them when they are experiencing feelings of rejection or exclusion (Leary, Tambor, T erdal, and Downs 1995). People experience increases in state self-esteem (momentary feelings of self-worth) and positive mood in response to inclusion experiences and decreases in state self-esteem and positive mood in response to exclusion experiences. In fact, people may be attuned more to decreases in perceived social acceptance than to increases in social acceptance (Leary, Haupt, Strausser, and Chokel 1998). This is because feelings of social rejection provide a signal for the rejected person to behave in ways that will increase their likelihood of social inclusion at the current time or in the future. For example, if a man perceives that he is being socially excluded, he may make a greater effort to increase his interaction partner’s liking for him. Alternately, he may be aggressive toward his rejector, temporarily sacrificing his need for acceptance but, perhaps, influencing the rejector and others to reconsider excluding him in the future.

Because people respond to experiences of social rejection in different fashions, researchers have investigated the influence of certain individual difference, or personality, variables on their reactions to instances of social inclusion, including, for example the influence of trait, or overall self-esteem, and rejection sensitivity (Downey and Feldman 1996) on people’s responses to exclusion feedback. Although trait self-esteem does not differentially influence people’s responses to exclusion, rejection sensitivity, a tendency to anxiously perceive and interpret social interactions as exclusion experiences, may do so. More specifically, people who are highly sensitive to rejection may respond to perceived exclusion experiences in ways that ultimately lead to continued negative social interactions. In contrast, people who are less sensitive to rejection may be both more likely to accurately identify rejection experiences and more adept at restoring positive interpersonal interactions.

RELATIONSHIP SATISFACTION

Satisfaction in close relationships is defined as the subjective attitude (satisfaction) and affective experience (happiness) in the evaluation of one’s relationship. Most of the existing research on this topic focuses on the correlates and predictors of satisfaction in married couples. The subjective perception of satisfaction is an important indicator of relationship quality and has consequences for the longevity of the relationship, as less satisfied relationships are more likely to end. Multidimensional analyses indicate that the structure of satisfaction is different for men and women. Men’s marital satisfaction usually can be determined by one factor that taps into overall happiness in the marriage (e.g., lack of regret over marrying, the amount of disagreement with their spouses on affection and sex). Women’s marital satisfaction, in contrast, appears to be two-dimensional. The first factor is overall happiness in the marriage, as with men, and the second dimension concerns the ways in which the couple relates to other people, including proper behavior with family members and friends.

In terms of stability, research by Carolyn Pape Cowan and Philip A. Cowan on the patterns of change in marital satisfaction (2000) shows that satisfaction is highest during the premarital and early years of marriage, then declines later. This decline holds true for both men and women, but appears to level off after several years. Despite this drop, couples that stay together often still report that they are happily married.

Research on predictors of relationship satisfaction has centered on intrapersonal, interpersonal/interactional, and environmental determinants of marital satisfaction. Researchers examining the intrapersonal determinants of relationship satisfaction investigate the ways personality characteristics of the members influence happiness in the context of the marriage. Analyses of differences and similarities between members of a couple reveal that “homogamy,” or partner similarity on different dimensions such as personality, emotionality, and values, predicts greater relationship stability and satisfaction. There is also evidence that specific personality characteristics of one or both of the members of the couple predict relationship satisfaction. Individuals who score high on the scale for emotional instability and those with negative views about themselves tend to have less satisfied partners. Similarly, Lilah Raynor Koski and Phillip R. Shaver in Satisfaction in Close Relationships (1997) note that in general, people with an insecure attachment style (i.e., those who doubt their own worthiness for love, as well as the dependability and availability of their partners) tend to have less satisfied spouses. It has also been shown, however, that attachment styles in men and women relate to relationship satisfaction somewhat differently. Women with an anxious attachment style (i.e., being preoccupied with relationships, and wanting extreme closeness and being afraid of being in love) experience lower levels of self- and partner satisfaction. Among men, in contrast, it is an avoidant attachment style (i.e., being uncomfortable with closeness, and dependency on other people) that predicts lower levels of self- and partner satisfaction. These personality differences relate to differences in communication and emotions. Securely attached men and women, who believe in their self-worth and have a trust in the availability of significant others for love and safety, appear to be more comfortable with self-disclosure, trust, and commitment, and report higher levels of positive emotions that are characteristic of satisfied relationships.

Researchers who focus on interpersonal and interactional correlates of marital satisfaction have observed that certain emotional and communication patterns are more prevalent among dissatisfied couples. One main finding is that it is the communication style between the partners, and not the number of conflicts per se, that predicts enduring relationship satisfaction. For example, Mari Clements, Allan Cordova, Howard Markman, and Jean-Philippe Laurenceau identified a pattern of “escalation-withdrawal-invalidation” in communication as detrimental to relationship satisfaction (1997). In this pattern, the couple allows negative interactions to spiral out of control and reach increasing levels of negativity. John Gottman in What Predicts Divorce? (1994) refers to a similar processes of “negative reciprocity” that prevents the couple from snapping out of the negative mood state the conflict has put them in. Such escalation and negative reciprocity is then followed by one or both members of the couple becoming less communicative (withdrawal). In the next phase, the couple usually engages in invalidation, whereby partners angrily assail each other’s character. Gottman’s research shows that a communication style characterized by a “demand-withdrawal” pattern is similarly maladaptive. The repetition of this pattern, in which one partner’s criticism, demands, or complaints produces defensiveness and passive inaction (stonewalling) in the other partner, erodes relationship satisfaction and ultimately leads to the dissolution of the relationship.

There is very little research on relationship satisfaction outside of heterosexual married couples. Based on the limited evidence available on same-sex partners, Gottman and his colleagues reported that there are many commonalities in the correlates of relationship satisfaction in homosexual and heterosexual relationships (Gottman, Levenson, Gross, et al. 2003). Consistent with findings on heterosexual couples, behavioral expressions of contempt, disgust, and defensiveness are related to lower levels of relationship satisfaction, whereas positive expressions,
such as humor and affection, are related to higher levels of relationship satisfaction in gay and lesbian couples.

In addition to the intrapersonal and interpersonal factors reviewed, environmental factors also affect relationship satisfaction. Life events such as the loss of a job or illness, as well as chronic stressors such as unemployment, can contribute to decreased levels of satisfaction. The effects of environmental factors can best be explained through their interaction with intrapersonal and interpersonal vulnerabilities, however. For example, although Cowan and Cowan reported significant drops in satisfaction around the time couples have their first child, couples who communicate better appear to be less vulnerable to erosion of marital satisfaction around this stressful time (2000).

Interventions aimed at increasing relationship satisfaction target maladaptive communication styles and/or negative emotions. For instance, therapeutic approaches try to change negative expectations about the partner and the relationship in order to enhance constructive discussion. Likewise, emotion-focused interventions attempt to enhance the understanding and down-regulation of negative emotions such as anger that hinder more constructive styles of coping with problems in the relationship.

RELATIVE DEPRIVATION

Nearly all theorists of social movements identify relative deprivation, rather than absolute deprivation, as the leading cause of revolution and rebellion. This accounts for the counterintuitive but persistent finding that typically such revolts are launched by groups that enjoy rising, not falling, socioeconomic conditions. However, two underlying questions remain the subject of academic inquiry. First is the specific definition of relative deprivation—namely, deprivation of what and relative to whom or what? The second is which factors mediate the connection between deprivation and rebellion—that is, when will relative deprivation actually lead to rebellion?

Aristotle wrote that people will rebel “if they think that they have too little although they are the equals of those who have more” (Davies 1971, p. 86). Marx typically focused narrowly on the relative material inequality between classes, predicting that workers would rebel even in the face of improving living standards if they perceived capitalist living standards to be rising even faster. Alexis de Tocqueville crucially observed that relative deprivation alone was insufficient; also necessary was an expectation that rebellion would improve the situation: “Evils which are patiently endured when they seem inevitable become intolerable when once the idea of escape from them is suggested” (Davies 1971, p. 135). This, he said, explained his empirical observation that revolution tended to occur when states were relaxing, not heightening, oppression.

In the early 1960s James C. Davies posited that the decisive relative deprivation was not between groups but rather between the expected satisfaction and actual satisfaction of one group. Rebellion was caused by “an intolerable gap between what people want and what they get,” so that it was “most likely to occur when a prolonged period of objective economic and social development is followed by a short period of sharp reversal” (Davies 1971, pp. 135–136). Like Tocqueville, he identified the key mediat-
ing factor between deprivation and rebellion as the expectation of success. "It is when the chains have been loosened somewhat, so that they can be cast off without a high probability of losing life, that people are put in a condition of rebelliousness" (Davies 1971, pp. 135–136).

Subsequently theorists such as Doug McAdam and Sidney Tarrow have emphasized the mediating role of "political opportunity structures" in determining when relative deprivation and mobilization actually will lead to actions such as rebellions (McAdam, Tarrow, and Tilly 2001). This work clearly echoes Tocqueville.

For more than three decades Ted Robert Gurr integrated these and other emergent findings of the literature into his repeatedly revised and expanded general theory of ethnocultural rebellion and political action. His primary causal variable continues to be relative deprivation, although he defines it broadly like Davies as the difference between perceived entitlement and actual welfare, so that even relatively privileged groups may be motivated to rebel by perceived disadvantage. Gurr (2000) says three mediating variables determine whether deprivation actually will lead a group to take action—salience of ethnocultural identity, group capacity for mobilization (based partly on geography), and political opportunities for success. A domestic political variable—whether state institutions and resources favor repression or accommodation of group demands—determines whether ethnopolitical action will take the form of peaceful protest or violent rebellion. Prominent economists and political scientists, including Paul Collier, Anke Hoeffler, David Laitin, and Jim Fearon, have disputed the primary role of relative deprivation in motivating rebellion, which they say is driven less by grievance than by greed.

RELATIVE INCOME HYPOTHESIS

Relative income hypothesis states that the satisfaction (or utility) an individual derives from a given consumption level depends on its relative magnitude in the society (e.g., relative to the average consumption) rather than its absolute level. It is based on a postulate that has long been acknowledged by psychologists and sociologists, namely that individuals care about status. In economics, relative income hypothesis is attributed to James Duesenberry, who investigated the implications of this idea for consumption behavior in his 1949 book titled Income, Saving and the Theory of Consumer Behavior.

At the time when Duesenberry wrote his book the dominant theory of consumption was the one developed by the English economist John Maynard Keynes, which was based on the hypothesis that individuals consume a decreasing, and save an increasing, percentage of their income as their income increases. This was indeed the pattern observed in cross-sectional consumption data: At a given point in time the rich in the population saved a higher fraction of their income than the poor did. However, Keynesian theory was contradicted by another empirical regularity: Aggregate saving rate did not grow over time as aggregate income grew. Duesenberry argued that relative income hypothesis could account for both the cross-sectional and time series evidence.

Duesenberry claimed that an individual’s utility index depended on the ratio of his or her consumption to a weighted average of the consumption of the others. From this he drew two conclusions: (1) aggregate saving rate is independent of aggregate income, which is consistent with the time series evidence; and (2) the propensity to save of an individual is an increasing function of his or her percentile position in the income distribution, which is consistent with the cross-sectional evidence.

Despite its intuitive and empirical appeal Duesenberry’s theory has not found wide acceptance and has been dominated by the life-cycle/permanent-income hypothesis of Franco Modigliani and Richard Brumberg (published in 1954) and Milton Friedman (1957). These closely related theories implied that consumption is an increasing function of the expected lifetime resources of an individual and could account for both the cross-sectional and time series evidence previously mentioned. However, starting with the 1970s, inability of these theories to explain some other puzzling empirical observations as well as the increasing evidence that people indeed seem to care about relative income have generated renewed interest in relative income hypothesis.

The first piece of evidence was presented in 1974 by Richard Easterlin, who found that self-reported happiness of individuals (i.e., subjective well-being) varies directly
Relative Surplus Value

with income at a given point in time but average well-being tends to be highly stable over time despite tremendous income growth. Easterlin argued that these patterns are consistent with the claim that an individual's well-being depends mostly on relative income rather than absolute income. Subsequent research, such as that published by Andrew Oswald in 1997, has accumulated abundant evidence in support of this claim.

Relative income hypothesis has also found some corroboration from indirect macroeconomic evidence. One of these is the observation that higher growth rates lead to higher saving rates, which is inconsistent with the life-cycle/permanent-income theory since the lifetime resources of an individual increases as growth rate increases. The work of Christopher Carroll, Jody Overland, and David N. Weil explains this observation with a growth model in which preferences depend negatively on the past consumption of the individual or on the past average consumption in the economy that is under the relative income hypothesis.

Another empirical observation that has been problematic for the life-cycle/permanent-income theory is the equity premium puzzle, which states that the observed difference between the return on equity and the return on riskless assets is too large to be explained by a plausible specification of the theory. Introducing past average consumption into the preferences accounts for this observation much better.

Relative income hypothesis has other important economic implications. Perhaps the most obvious implication is that consumption creates negative externalities in the society, which are not taken into account in individual decision-making. If individuals consume, and therefore work, to increase their status, then they will tend to work too much relative to the socially optimal level and hence income taxation could improve the social welfare.

Relative income hypothesis is a special case of negatively interdependent preferences according to which individuals care about both their absolute and relative material payoffs. In 2000 Levent Koçkesen, Efe Ok, and Rajiv Sethi showed that negatively interdependent preferences yield a higher material payoff than do selfish preferences in many strategic environments, which implies that evolution will tend to favor the emergence of negatively interdependent preferences. This could be regarded as one explanation for the empirical support behind relative income hypothesis.

RELATIVE SURPLUS VALUE

Relative surplus value is a concept introduced by Karl Marx in chapter 12 of the first volume of his book Capital (1867). One of the key objectives of this book was to explain the origins of capitalist profit. Marx argued that profits could not arise simply from trading between commodity owners because such trade was what von Neumann (1944) would later call a zero sum game. Instead, the source of profit had to be sought outside the sphere of circulation in the process of capitalist production. Here, labor power that had been purchased by the capitalist was set to work to make things. The amount of value created by the laborers would be proportional to the number of hours worked whereas the sum advanced by the capitalist to purchase labor power would be proportional to the value of that labor power itself as a commod-
ity. Laboring power was the ability to perform work, a concept analogous to Watt’s rating of the cotton mill engine’s ability to perform work in terms of normalized horsepower. Because the ability to perform work and the work actually done by employees are distinct, the zero sum game is avoided.

Marx argued that there were systematic processes in a capitalist economy that caused the value of labor power to be less than the value created during the working day. The first of these was the prolongation of working hours beyond preindustrial levels to twelve or fourteen hours a day. This lengthening of the day, which he termed absolute surplus value, was the principle source of profit during the early encroachments of capitalist production on an economic sector. During this phase the technology of production would be comparatively static, still depending on hand-operated tools.

The real revolution in production came with mechanization, which enabled the production of relative surplus value. Individual capitalists had an incentive to introduce new machinery because it gave them a competitive advantage. When power looms, for example, were first introduced, the mills using them could produce cloth using less labor than the competing hand-loom weavers. Because the market value of cloth was still regulated by the dominant hand looms, the powered mills earned higher profits. The hand-loom weavers were squeezed and eventually ruined by the process.

The surplus profit accruing to innovators was transitory, vanishing once the new technology was generally adopted, but it drove a process of continuous technical change. It was this change, operating at the level of the whole economy, that produced relative surplus value. Commodities entering into the consumption of the laboring classes—bread, coal, cotton clothing—were being constantly cheapened by innovation. This tended to reduce the value of labor power across the whole economy. The industrial revolution in textiles, mining, and mechanized agriculture had thus increased profits in all other sectors of the economy because labor power could now be purchased more cheaply. The constant efflux of impoverished handicraft producers onto the labor market also acted to force down wages. Accumulation of wealth by the new factory owners went hand in hand with an absolute immiserization of the mass of the population.

The possibility of innovator profit was always there, so the drive to produce relative surplus value was an invariant structural feature of capitalism. Unlike all previous exploiting classes, capitalists were forced to constantly transform the conditions of production. Constant revolutionizing of production, uninterrupted disturbance of all social conditions, everlasting uncertainty, and agitation distinguished the bourgeois epoch from all earlier ones.

The basic mechanism set out by Marx seems to accurately describe the broad economic transformation of the world economy over the nineteenth and twentieth centuries. Indeed, it seems more credible than ever in the epoch of globalization. However, taken at its face value, it would predict a constantly rising rate of surplus value over the period of capitalist history, and whether this has actually occurred is questionable. Evidence shows that the rise of surplus value due to mechanization has at times been offset by increased real wages. The production of relative surplus value may be seen as a process that interacts with other forces, including demographic ones, to regulate the overall level of profits. In countries with a stagnant or declining working population, shortages of labor power allow some of the gains of technological change to be transferred to the working classes. These factors were probably important in developed countries during the mid-twentieth century. The extent to which these offsetting tendencies will operate in the period of globalization is still an open question.

RELATIVES

SEE Family; Kinship.

RELATIVISM

Relativism, put very generally, states that a particular feature varies (or at least can vary) relative to certain phenomena. Prime candidates for the varying feature have been meaning, truth, rationality, justification, knowledge, value, and morality. Relativism thus arises in many areas of inquiry, and it has numerous variations within each area.

TRUTH AND REALITY

Relativism about truth states that truth varies relative to, for example, the concepts, the beliefs, the purposes, or the reasons possessed by an individual or a group. Relativists...
Relativism

about truth thus suggest that truth is, in a sense, always truth for an individual or a group with certain concepts, beliefs, purposes, or reasons. Cultural relativism about truth, for instance, implies that truths are true for a culture (perhaps in virtue of that culture's system of concepts, or conceptual scheme) but need not therefore be true for a different culture (say, with a different conceptual scheme). Relativism about truth, then, denies that truths obtain in virtue of reality independently of an individual's or a group's concepts, beliefs, purposes, or reasons. It thus opposes certain kinds of realism, or objectivism, about truth. Relativists must be cautious, however, not to suggest that their relativism about truth is true absolutely, or nonrelatively. If, however, relativism is true relatively, and not absolutely, opponents will find room for their absolutism about truth.

Concepts, truth-bearers, and statements are perhaps relative, regarding their existence, to a natural language or some other person-dependent phenomenon. This position seems coherent at least. Even so, we cannot thereby infer that what concepts, truth-bearers, or statements are about is similarly relative to person-dependent phenomena. Referring, describing, and explaining are perhaps relative to a natural language or some other person-dependent phenomenon, but it does not follow that the things about which one says something are similarly relative. Relativists and antirealists sometimes overlook this important lesson. It calls for a plausible distinction between human semantical activity and what such activity is about (e.g., objects, properties, states, or relations).

MORAL RELATIVISM

Morality has long been a prime candidate for relativism. Moral relativism, put very broadly, states that certain moral features vary relative to certain phenomena. Such moral features can include the basic moral beliefs accepted by an individual or a group, the basic moral requirements pertaining to an individual or a group, and the correctness of moral judgments or standards. Relativism corresponding to such moral features encompasses moral-belief relativism, moral-requirement relativism, and moral-correctness relativism. Moral-belief relativism can be assessed by empirical investigation, and is much less controversial than the other two versions.

Moral-requirement relativism entails that the moral requirements binding on a person depend on, and are relative to, the person's intentions, desires, or beliefs (or those of certain people in the person's society). Moral-requirement relativism has two common forms. Individual moral-requirement relativism states that an action is morally obligatory for a person if and only if that action is prescribed by the basic moral principles accepted by that person. Social moral-requirement relativism states that an action is morally obligatory for a person if and only if that action is prescribed by the basic moral principles accepted by that person's society.

Moral-correctness relativism states that moral judgments are not objectively correct or incorrect and thus that different people or societies can hold contradictory moral judgments without any incorrectness. In other words, what is morally correct for one person or group need not be correct for another person or group. Moral-correctness relativism can be developed with various accounts of "relative correctness," some of which do not imply that whatever moral judgments a person accepts are correct for that person.

Proponents of moral-correctness and moral-requirement relativism have based their case on various considerations, including moral tolerance. They sometimes stress that people should tolerate diverse moral views by allowing those views to be freely expressed. Even so, opponents of moral relativism need not disagree; they can hold that views conflicting with their own should be treated with full tolerance in terms of expression. In contrast, moral-correctness relativists cannot consistently hold that it is objectively correct that "a person morally ought to be tolerant of the views of others." Such relativists, then, may face a problem of tolerance in morality.

Some moral-requirement relativists hold that a moral requirement applies to a person only if that person accepts (perhaps implicitly) the requirement as reasonable for himself or herself. This view upholds a connection between (1) what is morally required of a person and (2) what that person approves of and has a convincing reason to do. Many relativists hold that a person's moral reasons (and thus moral requirements) have their basis in that person's own psychological attitudes, such as that person's desires, intentions, or beliefs. Gilbert Harman thus proposes that "for Hitler there might have been no [moral] reasons at all not to order the extermination of the Jews" (1975, p. 9). The underlying relativist position is inspired by David Hume (1711–1776); it claims that desire-independent objective principles of morality are inadequate as a source of moral reasons and that certain psychological attitudes (e.g., intentions) of a person are central to any source of moral reasons for that person. The opposite view is inspired by Immanuel Kant (1724–1804); it implies that desire-independent moral principles themselves can supply compelling moral reasons and requirements.

MOTIVATION AND RIGHTNESS

Is a person subject to a moral requirement only if that person has a psychological attitude, such as an intention, that recommends the satisfaction of that requirement? We can evidently "be subject" to a moral requirement in two ways: (1) as a motivating principle and (2) as a rightness-
determining principle. A moral requirement is a motivating principle for me if and only if I have, on the basis of my psychological attitudes, an inclination to satisfy that principle. In contrast, a moral requirement is a rightness-determining principle for me if and only if that principle determines whether an action I might perform is morally right. The first concerns motivation for a person; the second concerns moral rightness of an action for a person.

Relativism about the motivational efficacy of moral requirements does not entail relativism about the rightness-determining relevance of moral requirements. A person’s motivating psychological attitudes are not automatically morally obligatory or even morally permissible. For instance, Adolf Hitler’s psychological attitudes motivated him to wipe out millions of innocent Jewish people. Obviously, however, Hitler morally should have renounced those evil attitudes, given their role in bringing unjust harm to others.

According to a plausible nonrelativist view, the moral rightness of an action is determined by the action’s consistency with what is prescribed by the set of correct moral principles. Of course, we cannot quickly or easily specify the exact conditions for a moral principle’s belonging to the set of correct moral principles. The task is difficult. Even so, we need not finish that demanding task to recognize that a rightness-determining moral principle for a person does not depend on that person’s intending to satisfy that principle. A moral principle can be rightness-determining for me even if I intend not to act in accordance with it. Morality, as ordinarily understood, is intention-independent in this respect.

Some relativists will reply that there is no such thing as a “correct” moral principle in the sense suggested. These relativists, however, will need to identify the defect in the view that moral principles are correct in the sense suggested. In particular, they will need to show why we should not hold on to a robust notion of moral correctness. They must also specify, in this connection, the sense of “should” in the previous sentence in a way that fits with relativism. In response, nonrelativists will then be able to consider whether the resulting relativism is “true for them.” If it is not, they may proceed with their nonrelativism.

A general lesson emerges. Relativists must avoid a self-referential problem in their needed relativist notion of correctness: the problem that their notion of correctness either assumes nonrelativism about correctness or fails to challenge nonrelativism about correctness in virtue of allowing for absolutism about correctness. This is no easy task for relativists about correctness.

RELIABILITY, STATISTICAL

Statistical reliability refers to the consistency of measurement. According to Jum C. Nunnally and Ira H. Bernstein in their 1994 publication Psychometric Theory, in classical test theory reliability is defined mathematically as the ratio of true-score variance to total variance. A true score can be thought of as the score an individual would receive if the construct of interest were measured without error. If a researcher developed a perfect way to measure shyness, then each individual’s shyness score would be a true score. In the social sciences, constructs are virtually always measured with error, and as such true scores are unknowns that must be estimated by observed scores.

The expected standard deviation of scores for an individual taking a test many times is known as the standard error of measurement (SEM). The SEM of a score is estimated by

\[ SEM = s \sqrt{1 - r_{xx}} \]

where \( s \) is the between-groups standard deviation of scores on the test and \( r_{xx} \) is the estimate of score reliability. The expectation is that if an individual takes a test many times, 68 percent of scores will fall within one and 95 percent of scores will fall within two SEM’s of the observed score. Assume that Jamie scored 1,000 on a test with an observed standard deviation of 100 and a score reliability estimate of .84. The SEM for Jamie would be

\[ SEM = 100 \sqrt{1 - .84} \approx 40 \]

If Jamie took the achievement test many times, one would expect approximately 68 percent of the resulting scores to

RELIABILITY, STATISTICAL
fall between 960 and 1,040, and approximately 95 percent of the scores to fall between 920 and 1,080.

RELIABILITY AND ESTIMATES OF CONSISTENCY
